A concluding experiment was done in which 12 normal children received 6 oz. of a cold caffeine containing beverage on consecutive nights, the beverage containing 20 gm. sucrose and approximately 0.6 gr. caffeine. After determining the probable error on this series, it was shown that there was less activity in none of the children, an increase in 18.2 per cent of the children and in 81.8 per cent there was no effect noted. A companion experiment using 6 ounces of orangeade containing 20 gm. of sucrose was given to 12 normal children on consecutive nights. Deduc-

tions after determining the probable error on this series showed there was less activity in none of the children, an increased activity in 18.2 per cent of the children and in 81.8 per cent there was no effect noted whatsoever. Figure II shows the group averages for girls.

It is rather difficult to interpret these results properly. At the present time we have under way experiments collecting more data on these points. It seems fair to conclude, however, from the information we have now on hand that the administration of warm milk on retiring, which has been so long an empirical basis, is really effective. That this effect cannot be due to the temperature of the drink was shown by the fact that no such results were noted when warm water was substituted. That this was not due to the milk alone is shown by the fact that when milk was given cold, the results did not even approximate those obtained when given warm. It is assumed, therefore, that the warm milk effect must be a combination of both factors, that is, easily digestible and assimilable food given at a temperature approaching that of the body. Certainly, the administration of the other beverages named in no way seems to promote appreciably or to prevent sleep.

THE EFFECT OF FOOD ON CHILD'S SLEEP

This experiment was done on a series of 24 children in order to determine what might be the effect on sleep of the taking of various types of evening meals. Three types of meals were used, first, a normal meal which consisted of a fruit, cereal or eggs, and bread and butter and milk; second, a very heavy meal made up of first a fruit, then a meat such as steak or turkey, several vegetables, including green and starchy, dessert, such as pie or ice cream, and 1 oz. of candy to each child; third, a very light meal con-

FIGURE II

SHOWING EFFECT OF ORANGEADE AND COLD
CAFFEINE CONTAINING BEVERAGE ON
SLEEP PATTERN

sisting of simply a slice of bread and butter and a glass of milk. The evening meal was served always at 6:30 p.m. and the children retired at the usual hour of 8:30 p.m. From a study of these experiments with the heavy meal, sleep motility was found to be definitely increased in 23 out of the 24 children. The group average for girls is shown in Figure III.

As regards the light meal in comparison with the normal supper, it will be noted there was very little, if any, difference. On the average, the children went to sleep just as quickly with a light meal as they did with a normal meal and their general sleep movement throughout the night was practically unchanged. In the case of the heavy meals a very high percentage of the children showed a much greater increase

in movement than was seen after any of the beverage experiments. Expressed in terms of the probable error, it was found that after the very light evening meal sleep seemed to be promoted in 25 per cent of the children; restlessness was seen in 8.1 per cent and in 66.7 per cent of the children the meal seemed to have no effect. In the case of the heavy meal, from the standpoint of the probable error, none of the children slept as quietly; there was an increased restlessness in 58.3 per cent of the children and no effect was noted in 41.7 per cent of the children. This restlessness after a heavy evening meal was especially noticeable in the first hour after retiring and on the average extended practically throughout the night. In the case of the girls during only 1 hour did the sleep motility fall to normal, and with the boys, this fall was delayed to the 8th and 9th hour after retiring.

CONCLUSIONS

From the above we may conclude the following:

A child has a very definite individual sleep pattern.

The drinking of 6 oz. of warm milk at bedtime seems to produce quiet sleep in normal children.

Of the several other beverages tested none seems to affect sleep consistently. The ingestion of a beverage containing 0.6 gr. caffeine and 20 gm. sucrose proved to be identical in effect with the drinking of 6 oz. of orange juice containing the same amount of sugar.

The eating of a heavy evening meal by children between the ages of 9 and 14 years produces marked rest-

FIGURE III
SHOWING EFFECT OF HEAVY MEAL AND LIGHT MEAL ON SLEEP PATTERN

lessness. In many cases the restlessness continued throughout the night. The eating of a very light evening meal differs in no respect from the sleep seen after a child has eaten its normal supper.

Relative Values in Tuberculosis Case Finding Work

H. E. KLEINSCHMIDT, M.D., F.A.P.H.A.

Director, Health Education, National Tuberculosis Association, New York, N. Y.

NUMEROUS communities have recently undertaken tuberculosis case finding work by the method of making tuberculin tests of school children and examining the positive reactors with the X-ray. Some skepticism as to the value of this method (we shall call it the "tuberculin-X-ray" method in this article) has been voiced because the results are not so "productive" as the older method of confining the examination to contacts of open cases ("contact-examination" method). The two methods should be evaluated from a public health administration standpoint, but it is an error to try to balance one against the other with the idea of selecting one method to the exclusion of the other.

The first necessary step in the control of tuberculosis is the discovery of cases, for each case is a real or potential "carrier." In 1897 Dr. Hermann Biggs secured legislation requiring the registration of all cases of tuberculosis in New York City. This innovation met with bitter opposition but prevailed in the end, and the plan in one form or another has since been adopted by every state in the Union. The theory on which the reporting plan is based is that if all doctors report all cases that come to notice the health department will soon have a complete roster of all carriers of tuberculosis. Reporting is a vast net spread over the community to catch the disseminators of the tubercle bacillus.

In a previous article¹ some of the

many holes in this net were pointed out. One conclusion was that, for the country as a whole, case reporting is less than 50 per cent complete. Even where case reporting is well done quantitatively its full qualitative value is not realized. For example, Plunkett² reported that in 1925, only 24.2 per cent of the tuberculosis cases known to the New York State Health Department were registered 1 year or more before death. To be sure, delayed reports, even those made after death, are valuable because they enable the health department to trace out contacts, but, assuming the infectious period of a case to average about 2 years, the delay in reporting three-fourths of the cases means that many people are exposed to the disease who might be spared that danger if reporting were more prompt.

By examining the contacts of known cases of tuberculosis we discover new cases. The system is like a chain letter, which, if it could be carried on without a break would ultimately reach the entire population. Tuberculosis and chest clinics appreciate the importance of contact examination. It is a tradition among them that when a case of tuberculosis is diagnosed every effort must be made to get all members of the household examined. How efficiently does the plan work in a well conducted clinic?

A study of the effectiveness of contact work was recently made by analyzing the records of the clinic patients of Henry Phipps Institute in

Philadelphia.³ All patients who were diagnosed as tuberculous for the first time during a selected period of 18 months were designated as "original tuberculosis patients." These numbered 182, and the family record of each was reviewed 1 year after the date of diagnosis. This gave a picture of the success of 1 year's attempt to secure the examination of contacts. It was found that there were 647 contacts of which 308 (48 per cent) came to the clinic within the year after the date of diagnosis of the original tuberculosis patient.

Of the 308 contacts who did come for examination, 35 (11 per cent) were found to have tuberculosis. Obviously the contact examination work as carried on by this clinic was "productive"; for a clinic to discover in 1 year 35 cases of hitherto unknown tuberculosis, to say nothing of the more intangible beneficial results, is indeed commendable.

Reducing the above findings to round-number ratios we may say that for each 10 original tuberculosis patients known to the clinic there were: (a) 35 contacts, of whom (b) 17 were persuaded to come for an examination, of whom (c) 2 were found to have tuberculosis.

Excellent as this result is, it leaves much to be desired, judged by standards of administrative efficiency. Since more than half of the contacts failed to come to the clinic for examination, the disquieting question arises, how many of these are tuberculous? If the same ratio holds for them as for the group examined we may infer that for each 10 original tuberculosis patients there are among their contacts at least 2 undiscovered cases of tuberculosis.

Whatever its shortcomings contact-examination work probably exceeds in importance any other single measure in the tuberculosis program. But since it is not inclusive enough to be relied upon

as our sole means of discovering cases, supplementary methods are, to say the least, desirable. One such measure is the routine examination of school children with tuberculin followed by roentgenographs of the positive reactors. The experiences of communities with this method are numerous and essentially similar. One of the latest reports is that of the Chadwick Clinics in Massachusetts.⁴ Among children aged 15 to 19 years who were examined in 17 Massachusetts cities, pulmonary tuberculosis was found in 65 out of each 10,000 who reacted to the tuberculin test and who were X-rayed. This is in the ratio of 1 case per 154 examined by X-ray.

To indict the tuberculin-X-ray method as "unproductive" merely because it discovers only 1 case of tuberculosis out of each 154 X-ray examinations, whereas the yield of contact-examination work is 1 case out of 9 contacts examined, would be superficial and unjust. There are other considerations to be taken into account and other values to be compared, such for example as the relative costs of the two methods, the personnel required, and the equipment needed. Since these differences are at the present time difficult to calculate we may content ourselves with an enumeration of some of the values of the tuberculin-X-ray method.

1. Group tuberculin testing and X-ray examination of the reactors can be systematized so as to entail relatively little labor and expense. (X-rays in groups can be secured for as little as \$.75 per case.)

2. The tuberculin-X-ray method aims not only to discover pulmonary tuberculosis of the adult type among children but also significant lesions of the childhood type. Hetherington⁵ and his associates found significant lesions in 1.0 per cent of white boys 12 to 20 years of age; and 2.3 per cent of white girls of

the same age in a study of school children in Philadelphia. (The authors include in the grouping of "significant lesions" calcified lesions of the lungs or tracheobronchial lymph nodes, which may indicate heavy initial exposure to tubercle bacilli, and caseated lymph nodes, which represent a large tuberculous focus without evidence of healing and which lesions have grave significance until calcification has occurred.)

Generally speaking, the presence of childhood type lesions of whatever stage warrants the tentative presumption that the child has been exposed to mass dosage of tubercle bacilli. For the majority of children with childhood type lesions the serious danger confronting them is not the lesion *per se* but continued exposure if such exists. Until that question has been cleared up and until the contact, if it is established, is broken, the child is to be regarded as being in danger of developing serious tuberculous disease.

3. Discovering tuberculosis in children of the teen age is extremely valuable for it is at that time that the prognosis is most hopeful. The teen age sector is a strategic one because it is in the age period 15-25 that the tuberculosis mortality shows its sharpest rise. To prevent a case of tuberculosis is far better than to discover a case.

4. By means of the tuberculin-X-ray method many cases are discovered which are symptomless. Of 130 pulmonary cases found in the Chadwick Clinics during a 5 year period, only 8 per cent gave definite symptoms, and barely 50 per cent showed either symptoms or physical signs. One of the three main obstacles met in endeavoring to secure contact examinations at the Henry Phipps Clinic is that the contact says he feels well and sees no need for examination.

5. Follow-up work, which is an essential part of the tuberculin-X-ray method, leads the investigator into many

a home where there is an open case of tuberculosis, undiagnosed or masquerading as bronchitis, heart disease, or something else.

Dr. F. E. Harrington,⁶ Commissioner of Health of Minneapolis, states that 26 per cent of the cases of adult type of tuberculosis now registered have come to the department's knowledge through follow-up work originating with infected children discovered in routine tuberculin-X-ray work.

6. The tuberculin-X-ray method has enormous educational value. Those who toil in the field of health education know how great is the inertia of indifference and how difficult it is to arouse interest in the subject of tuberculosis. The dramatic power of "consumption" has largely been lost—for which we should be grateful. Yet the need for understanding and for intelligent action is still great. By what means shall we reawaken interest and create a thirst for knowledge? A well planned project of case finding by the tuberculin-X-ray method breaks down the barriers and opens wide the gates for the education we wish to impart. Merely to ask parental permission to do the tuberculin test raises the question in their minds, "Why should *my* child be tested?" Willingly they come to hear a talk on the subject; eagerly they read the pamphlets offered them. Incidentally, it puts us on our mettle to express simply and truthfully but without creating unfounded fear, what the significance of infection may be. When the child's reaction turns out to be positive, they invite even more pertinent explanation. The commercial advertiser speaks of "breaking down sales resistance" and considers his campaign half won when he succeeds in doing it. Parents who will listen can easily be persuaded to surround the child with safeguards and good home environment, and to utilize the family doctor as health adviser.

Doctors who have given scant attention to tuberculosis are impelled to renew their interest and their knowledge when parents come to them with the child and a report from the school indicating what the tuberculin test and X-ray disclosed. The doctor's interest in the child necessarily embraces the entire family situation. The family becomes the unit of his study. Furthermore, he relates the childhood lesions called to his attention to the broad subject of tuberculosis. For the past 3 years a publication of the National Tuberculosis Association known as *Childhood Type of Tuberculosis* has been in great demand among physicians, which reflects widespread interest in this particular subject.

Through a school tuberculin test survey, teachers and school officials become acquainted with the problem of tuberculosis. Students in the high school are eager to learn about tuberculosis when such tangible evidence as a positive reaction or an X-ray film is before their eyes.

7. Finally, tuberculin test surveys contribute much needed knowledge to our understanding of the perplexing problem of tuberculosis. We sorely need, not only more research into the pathology of tuberculosis but also epidemiological observations made on large numbers of children in different localities, and the base lines now being established by group studies will be invaluable a few years hence when the time factor will have exerted its influence.

SUMMARY

The tuberculin-X-ray method is not a substitute for the tried and tested method of contact examination. On the other hand, contact examinations cannot be expected to reach certain sectors which are successfully explored

by the tuberculin-X-ray method. Both methods have values. But these values cannot well be compared on a basis of relative efficiency. Therefore, both methods should be employed at least until displaced by some better scheme. Where means and facilities are limited it goes without saying that contact examination work should be given precedence—it is the most obvious method to be employed. If possible, tuberculin-X-ray surveys of high school children should be made as a supplement. For those who are able to do still more, elementary school children should be given the benefit of the tuberculin test and the X-ray.

With the continued decline in the incidence and death rates of tuberculosis, the possibilities of reducing it to a controllable minimum grows ever more attainable. Yet, as the fight narrows down, it becomes more technically difficult. We have succeeded thus far in discovering the obvious "carriers." There are still among us a goodly proportion of concealed or unsuspected cases. If the modern search for contacts seems tedious, complicated, and round-about, our justification is that only by reducing the foci of infection to a vanishing point can we hope to achieve protection against this disease in the same measure as we now enjoy protection against yellow fever.

A Plan to Increase Understanding of the Value of Scientific Medicine^{*}

T. J. EDMONDS

Executive Secretary, Iowa Tuberculosis Association, Des Moines, Ia.

THE subject shows a sense of opportunism on the part of the program makers. Let us analyze it—starting at the rear end. After the third reading of it in a quiet darkened room the following break-up into questions emerges:

1. How scientific is medicine?
2. If it is scientific, of course, it has value. But do we want to increase popular understanding of its value?
3. Does the topic mean merely to increase the feeling that it is valuable, or to increase popular knowledge of the facts of medical science?
4. Can we do one without doing the other?
5. Can we do both at the same time?
6. If we can and should increase such understanding how shall we do it?
 - a. With limited funds?
 - b. With ample funds?

How scientific is science?

I asked this question of a doctor. I must have caught him either in a frank and cynical mood, or just after an examination of his bank account; for he declared that if half of the diagnoses made by licensed physicians were correct, that would be a good batting average. I asked the question of a business man interested in advertising and well acquainted with health and medical problems. He said he thought the doctors were right about 90 per cent

of the time. He said he had acquired more faith in the intelligence of physicians after having had some experiences with experts in other lines. He then stated that lawyers must be wrong exactly 50 per cent of the time, because in every trial one side loses and the other wins; and possibly the one who is right in the lower courts turns out to be wrong in the appeal courts; and more than that, if you give even a supreme court years enough it will reverse its earlier diagnosis.

My personal experience with doctors has been one which prejudices me in their favor. We have spent considerable money with a child specialist, but it has been in the nature of insurance. Our 2 girls, one in kindergarten and one 3½, have never had anything more serious than colds. They were vaccinated and immunized in infancy.

I am convinced that my one good eye, which, although age has rendered it unwise for me to scan the sidewalks while driving through a busy city street, still serves me well in avoiding berserk trucks, in reading in bed, and in absorbing the joy of a sunset, can be credited to my frequent consultation of a good oculist.

But whatever may be our personal experiences, the newspapers are full of remarkable successes in surgery; the vital statistics tell the story of diminished death rates which must be credited, if not to scientific medicine, at least to social reforms and to preventive public health measures made possible

^{*} Read before the Public Health Education Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

by the facts furnished through the research of scientific medicine.

That motherhood is in the majority of cases safe and normal, that children can be expected to reach maturity, that tuberculosis can be arrested, are facts that can be counted on with greater certainty than that XYZ tires will not blow out and that runless stockings will remain stationary.

Of course it is true that not every doctor is a scientist. Some are just practitioners—some are just psychologists. And it may also be true that the man who lives in a city and deals with specialists is more impressed with the correctness of medical diagnosis—and perhaps more impressed with the much discussed problem of the cost of medical care.

It is equally true that not every business man is a business man—and recent events have suggested that perhaps you can't always bank on bankers.

So in this world of chance and approximations and trial and error, scientific medicine in the field of health is the only thing in which the public can place a fair degree of confidence.

Shall medicine be publicized?

The ancient tradition of medical ethics, that the private physician should not advertise, is based on sound business principles. Personal fitness is not the sort of thing that can be advertised. Doctor advertising might degenerate into ads like this:

B. C. Hippocrates, M.D.
Member Elite Country Club
Drives a Rolls-Royce
All the latest equipment in his office
Has a perfect bedside manner
Is absolutely sterile

In the building where I have my office there was once a chiropractor who hung out a sign which read:

Dr. A. B. Blank, D. C.
Specialist in everything
Whatever ails you
I can treat it

One night the specialist folded up his tent and departed, to—as far as I know—the never-never land.

Business firms can advertise because they handle merchandise, not personal service only. Businesses can advertise because they have only a few competitors; but a city which contains 1 department store lists 200 physicians.

The medical profession as a unit can engage in what is known to the cult of publicists as institutional advertising. It can advertise the field of medical service as a whole, that is, if certain conditions be fulfilled.

If medicine is a hocus-pocus, a matter of magic or mystery, it were best not subjected to the white light of publicity. But modern scientific medicine is not that. If the majority of doctors do not know how to give a complete medical examination, it might be best not to engage in the periodic examination propaganda. If the medical profession cannot render the service which it offers, it had best not advertise. But the profession rightly claims that its service is as accurate and efficient as the average well advertised commercial product or service. What reason therefore is there for not telling the public of the value of scientific medicine? No valid one that I can think of.

The advantages of making the public conscious of its need for medical advice and care are many. The doctor must live—and if the public is doctor-conscious he can live better. The patient-public wants to live as long and as fully as possible—and if he uses his doctor freely and constantly both in prevention and cure he is likely to do both.

Is it not the duty of the medical profession, then, to help increase the public understanding of the value of scientific medicine?

Shall the public have the facts?

While we still just love to take our

religion and our politics on faith, we are rebelling about swallowing our medicine and our automobiles that way. No longer is the patient content with being told that he has something with a long Latin name. The art of reading learned in our communistic schools, the newspaper and the radio, have made us want to be partners in the discoveries of science as well as in the problems of government and finance. It would be wasted effort to try to sell the idea that scientific medicine is valuable without explaining what scientific medicine is. As a matter of fact we cannot popularize scientific medicine without paying said public the compliment of revealing some of medicine's mysteries.

How shall we do it?

In the typical city there are 4 agencies that are ready-made instruments of propaganda:

The county medical society or academy of medicine

The official public health service

The voluntary health organization

The insurance companies, the dairy companies, and other business interests which profit by the reduction of health hazards.

I have called these instruments rather than media. The publicity media of course are familiar to all of us—the newspaper, the house organ, direct mail, the radio, group speaking, the motion picture, graphic art, demonstrations, and person-to-person publicity. The means of using these media are so well known to public health people that it would seem best to take judicial notice of that fact and confine our discussion to the general outlines of the plan.

There is some difference of opinion among physicians as to how far a county medical society can go in promoting public health, and the unavoidable corollary of such effort—the enhanced fortunes of the profession. The New York Academy of Medicine is an example of what might be called the

liberal tendency. But, whatever may be the inhibitions of the board of governors of a medical society, it certainly can do much through other agencies. In so doing it can furnish the initial motivation through suggestion and organization and can very properly contribute financial support.

The private organization should have a fair proportion of doctors on its board of directors. The National Tuberculosis Association executive committee is made up almost entirely of physicians, and the boards of state and local associations contain enough to give them proper scientific medical guidance. The spokesmen of the medical profession in the country have asserted that it is the duty of the medical profession to assume the leadership in public health movements through active participation in the affairs of voluntary agencies and of the official public health service.

There is in the average community a ready-made instrument of health publicity. It is the tuberculosis association, or in the big cities, the public health federation of which the tuberculosis society is a unit. The chief function of the tuberculosis association is prevention through education. Education is a broad term, extending all the way from ordinary news publicity to child health training methods and the professional postgraduate clinic. It embraces the use of all the media mentioned above.

The tuberculosis movement affords a very comprehensive example of a program of increasing popular understanding of the value of scientific medicine. It has all the earmarks of the modern orthodox PLAN. It has a three-initial label—EDC, early diagnosis campaign, recently changed to SEC, spring educational campaign. It has its trademark—the red double-barred cross, international emblem of the anti-tuberculosis crusade. It is generously

supplied with slogans, such as "Let your doctor decide"; "Every case comes from another"; "Tuberculosis doesn't just happen"; "Protect your child"; "Tuberculosis—the foe of youth"; and an unaccepted one "The early diagnosis catches the germ." It utilizes all the known media. During April thousands of short popular pamphlets are distributed, groups are addressed by speakers, broadcasts are made, small posters and 24-sheet panels are displayed, news is manufactured, magazine articles are placed, and extra clinical service is given.

Now the EDC plan could be spread—without a great deal of thinning—throughout the entire year and could be made to include not only tuberculosis but the entire range of human ills which are susceptible of diminution through preventive efforts. As a matter of fact the National Tuberculosis Association recommends such extension.

The official agency probably does not think its chief function is publicity and education, but on analysis it appears to be. The health department which promotes a community-wide diphtheria immunization project is saving itself the later job of individual case work. One of the best things done by the Iowa State Department of Health is the few minutes a week spent by a doctor with ink in his blood who writes a news release known as a weekly health message. It goes direct to all the 660 papers in the state and often receives as high as a 90 per cent acceptance. The local health department takes advantage of hot news events to add its localized public advice and comment.

The state medical society maintains a speakers' bureau, furnishing, usually at its own expense, physicians who are supposed to be able to talk in popular terms to such interested lay gatherings as women's clubs and noontday men's groups.

The county public hospital and sana-

torium would furnish an excellent laboratory for propaganda if there were in the community a health minded publicity expert given opportunity to use it.

As an example of the part played by business concerns organized for profit, a county coöperative dairy association conducts a weekly broadcast on the health value of milk, methods of insuring purity, milk-borne diseases, and the diet of children. Everyone has seen the advertising in magazines donated by a great insurance company to the cause of public health. As a matter of fact every good insurance man is a salesman of public health. The interests of insurance and of public health are identical—each wants to keep policy holders alive and healthy.

A local plan with limited funds

Now as to the machinery of the set-up, first with limited funds. Stimulated, approved, and assisted by the county medical group the local tuberculosis association can lay out a year round program of popular education. Speakers can be furnished by the medical society and can be lined up easily in other ways. Men like to speak—so do women, it is currently reported. Literature can be distributed. Demonstrations can be arranged. The radio welcomes such a popular subject as health. But in the program it must not be forgotten that after all advertising loses its effectiveness unless the goods it sells are delivered and unless the goods are good. The service rendered by clinics, by visiting nurse associations, by the medical care of the sick poor in their homes, by the public hospital, by the local department of health, must be the best that can be given. The most effective publicity is now, as it always has been from the days of Adam and Eve and the snake salesman, the word-of-mouth person-to-person touch.

Financial campaigns even have their value as educational forces. News-

papers are generous with their space during a community chest drive. The most appealing talking points are visiting nursing and child health. Health work is free from the necessity of much explaining which frequently surrounds the character-building or group social work agency, and at the same time it is not a ready target of criticism as is the relief or family welfare agency. The annual Christmas Seal campaign is primarily an educational device. Its news and graphic publicity is largely a process of adult health education, and its mail sale letters are a still more direct piece of health consciousness selling. It is of real advantage to a community chest to encourage a separate general seal sale, whether or not it underwrites part of the tuberculosis society's budget; because the seal sale is a social service; because the seal sale appeals to the Christmas season generosity urge; because the seal sale is a voluntary process; because the seal sale is democratic in that it obtains small sums from a general cross-section of givers, many of them people not reached by the community chest drive; and because it adds much to the funds available for the local social work program in which the chest is interested without detracting at all from the amounts pledged to the chest.

In all this thought about the tuberculosis society being made the center from which the publicity and educational forces designed to popularize scientific medicine emanate, I am assuming that the tuberculosis organization has either a secretary or an assistant who has training or ability in social work publicity. That is necessary to the proper functioning of any tuberculosis organization.

Such a publicity secretary should function with 2 advisory boards or committees—a social work publicity council, and a health council. He should draw upon the advertising club and the news-

paper fraternity for advice and aid; he should be directed in matters scientific by the medical profession and the public health service; he should cooperate with the many voluntary non-operative organizations which are interested in public health. Speaking of this last, the women's clubs, the men's service clubs, the parent-teacher association, the American Legion, the farm bureau, and several other large and influential groups have some sort of a health program of their own which can be jigsawed into a fine picture of health propaganda.

Such is a possible plan where funds are limited. It is the plan applicable to the average community.

It is pleasant, of course, though not profitable, to speculate upon what could be done with ample funds. The county medical society could employ a social work publicity expert, with adequate staff, or retain the services of a publicity agency. The voluntary health agencies and the public health department and the schools could be subsidized. A program could be prepared that would rival the popularity and effectiveness of dated potables, and fags that do not fag the throat, and remedies that rim that oncoming cold. Such a propaganda would possess the additional advantage that it could always deliver the goods—because there is no longer any possibility of disputing the figures that prove the value of clean water, pure milk, and childhood immunizations.

CONCLUSION

It is a great cause—that of prevention through the increase of public understanding of the value of scientific medicine.

Once a president of the Iowa State Medical Society, Dr. W. A. Rolfe, waxed eloquent in a presidential address that was different from most:

Great is the science that contemplates impenetrable space and studies the whirling

worlds, each in its own sphere, as they have leaped into space from the finger tips of God's creative genius; but greater is that science that snatches from space the mysterious element and applies it that the blind may be made to see and the lame to leap with joy.

Great is that science that delves into the bowels of the earth and seeks to find there the footprints of the Creator, left ages and ages ago in the form of leaf, or flower, or fish, upon the surface of solid rock, or that delves into the earth and seeks to find things of material and industrial value to humanity; but greater is that science that delves into the dark realms of the earth's bosom and seeks for those elements that may be used to alleviate human suffering. Great is that science that seeks to classify the green verdure of the earth, from the modest violet to the sturdy oak, the swaying elm, the weeping willow and the clinging vine; but greater is the science that seeks to find in root, in branch, in leaf, in flower, in fruit, the elements that may be used to smooth the wrinkles from the human pillow of pain, to lull to sweet and peaceful sleep the weary, tired, bewildered brain. Grand is that science, profession, or calling that anchors upon the dark, dim, distant horizon of the future beyond the grave, that bright and brilliant star of hope for life eternal; but grander is that profession

that robs the grave of its victim, and restores the infant, laughing, in childish health and glee, back to a grateful, happy, loving mother's arms.

This—and the occasion—and the iced tea—inspired me to indite the following paraphrase of Dr. Rolfe's eulogium:

Great is the doctor that with the magic of drugs lessens pain; but greater still the physician of the future who prevents human suffering. Great the healer that makes the blind to see; but greater the far-seeing physician that with a simple drop or two of liquid in the eyes of the new-born child makes sure that he shall never lose the green of trees and grass and the blue of summer skies. Great is the physician that guides the mother through the valley of the shadow; but greater yet the guardian of motherhood whose wise care lifts the shadow of fear and pain from that valley. Great is the doctor of yesterday who cured; but greater the doctor of tomorrow who cares so constantly that cure shall not be needed.

Great is the doctor of today who has added years to the life we live; but greater the doctor of tomorrow who adds life to the years we live.

Italy—National Bureau of Maternal and Child Welfare

THE Central Council of the National Bureau of Maternal and Child Welfare of Italy recently approved its budget for 1934, providing a government appropriation of 100 million lire. In addition the bureau expects to derive 12 million lire from other sources, among them membership dues.

The bureau is permitted by law to have dues-paying members; the bureau may also receive gifts from private sources; in 1933 these gifts amounted to one and a half million lire.

Fifty-six per cent of the bureau's appropriation for 1934 is to be used for work with married mothers and

children born in wedlock, and 35 per cent for unmarried mothers and children born out of wedlock. As in previous years, the bureau is to give special attention to the prevention of morbidity and mortality of mothers and children and the encouragement of marriages and births.

In accordance with the experiment on financial decentralization begun in 1933, the money will be divided among the provincial branches of the bureau in proportion to the population and economic conditions of each province.—*Rassegna della Previdenza Sociale*, Rome, Dec., 1933.

Rabies Vaccine Protection Tests*

JOHN REICHEL, F.A.P.H.A., AND J. E. SCHNEIDER
Mulford Biological Laboratories, Sharp & Dohme, Glenolden, Pa.

THE many attempts to establish the potency and efficacy of rabies vaccine by animal protection tests have generally failed to yield consistent results, because of difficulties experienced with the infective dose. The dose is usually either too severe or innocuous, depending on the amount and mode of injection. Intracranial and intraocular injections of a proper dose invariably prove fatal. Other modes of infection—subcutaneous, intravenous, intramuscular, natural or artificial exposure—are so uncertain that similar results cannot be repeatedly obtained with any degree of consistency.

The intracranial injection is most direct, and the intraocular only a trifle less so, from the viewpoint of the distance the virus has to travel from the injection point to the brain tissue. A little further removed, however, is the oral region, and for this reason we selected the tongue as the repository for the infective dose, in the intralingual method of injection.

The method consists in the proper restraint of the animal, under anesthesia or narcosis. The rabbit may be placed in a suitably sized box with a hole at one end allowing for the protrusion of the head. By the use of a mouth speculum or rings with chains, the jaws can be held apart and the tongue grasped with a pair of forceps. We prefer to inject 0.1 c.c. of a 5 per cent emulsion of brain tissue virus moder-

ately deep into the tongue, to one side of the median line, so that a bleb is noticeable. The animal apparently is not inconvenienced immediately or later by the injection and the period of incubation is only slightly longer than that following intracranial injection. Of two sets of rabbits the one injected intracranially averaged a period of incubation of 6 to 7 days, while the other with the same dose intralingually averaged 8 to 9 days. Of the total number injected intralingually 20 per cent survived, while of an equal number injected intracranially 100 per cent promptly developed rabies. Occasionally will an older rabbit survive the intracranial infective dose.

The rabies vaccine protection test is conducted by the subcutaneous injection of 3, 5, or more rabbits with the vaccine, followed 21 days later by the infective dose of virus intralingually. The test rabbits and an equal number of virus injected control rabbits are held under observation for 14 days.

The preparation of the infective dose of fixed rabies virus is an important detail. The rabbit brain tissue "seed" virus, usually kept in 50 per cent glycerine, is emulsified and injected intracranially into a rabbit and when it is moribund, so timed that this will occur on the day the infective dose falls due, it is chloroformed, the brain removed, immediately ground and made up in a 5 per cent emulsion in normal salt solution. The emulsion is strained through a 60 mesh silk and promptly used in 0.1 c.c. amounts.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

TABLE I
RABIES VACCINE PROTECTION TEST ON RABBITS

Group	Rabbits	Rabies Vaccine	Interval	Infective Dose†	Results
1	8	(a) 2.4 c.c. 14 days*	14 days	0.1 c.c. Intra- lingually	Living 100%
2	8	(b) 4 c.c. 14 days†	14 days		Living 100%
3	5	Controls			Living 20% Dead** 80%

* 33⅓% Brain tissue emulsion rabies vaccine (chloroform killed) daily injection.

† 20% Brain tissue emulsion rabies vaccine (phenol killed) daily injection.

‡ 5% Brain tissue emulsion rabies virus.

** Deaths preceded by definite symptoms of rabies.

The rabies vaccine protection test applied to two vaccines, one (a) chloroform killed and the other (b) phenol killed yielded comparable results.

The (a) chloroform killed vaccine tested included 17 brains and cords of rabbits moribund with rabies, which were ground, and 2 c.c. of buffered salt solution added to each gm. of tissue to make a 33⅓ per cent emulsion to which 1 per cent chloroform was added. The emulsion was kept at room temperature and shaken daily for 30 days. Two rabbits survived intracranial injections of 0.1 c.c. doses.

The (b) phenol killed vaccine tested included 20 brains and cords of rabbits moribund with rabies, which were ground and 4 c.c. of buffered salt solution added to each gm. of tissue to make a 20 per cent emulsion to which 1 per cent phenol was added. The emulsion was kept in an incubator for 72 hours at 37.5° C. Two rabbits survived intracranial injections of 0.1 c.c. doses.

Both vaccines (a) and (b) prepared on 11-27-31 were kept in cold storage and potency tested on 11-28-32, 1 year later, as shown in Table I.

Table I shows that all of the 16 rabbits injected with vaccines (a) and

(b) survived the infective dose, which killed 4 of the 5 controls.

Rabies vaccine protection tests were conducted on mixtures made from samples of rabies vaccine phenol killed, 5 per cent brain tissue emulsion, that are taken and set aside at room temperature, as a routine procedure from each batch prepared.

The rabies vaccine mixtures for 1929, 1930, and 1931 were made from mixed samples of rabies vaccine prepared during the first 6 months of each year. For 1932, two mixtures of rabies vaccine were made, one from samples of batches prepared during the first 6 months, and the other from those prepared during the second 6 months. The mixture for 1933 was made from samples taken from rabies vaccine prepared during the first 3 months.

The normal rabbit brain tissue emulsion was a freshly prepared 5 per cent emulsion.

The vaccine and normal brain tissue emulsion were tested on rabbits as shown in Table II.

The test shows that rabies vaccines (1929 and 1930) exposed to room temperature longer than 2 years, failed to protect rabbits. Rabies vaccines (1931, 1932, and 1933) protected the

rabbits. Normal rabbit brain emulsion did not protect rabbits and 83 per cent of the control rabbits died of the infective dose.

The rabies vaccine protection test was used to determine the number of daily doses of rabies vaccine phenol killed, 25 per cent brain tissue emulsion required to protect rabbits against an infective dose, and also to determine the duration of such protection.

Table III shows the results of three tests. The first, 7-19-32, is the original; the second, 1-5-33, was made on the rabbits surviving the first test, and the third, 7-21-33, on rabbits surviving the first and second tests. The rabies vaccine phenol killed tested was prepared 6-26-32. It was shown to be noninfective as 3 rabbits survived 0.1 c.c. doses injected intracranially. The rabbits injected with 4 daily injections, all died of the infective dose given 17 days later.

The rabbits injected with 7 daily injections survived the first infective dose but not the second 5½ months later, indicating that protection did not last 5½ months.

The rabbits injected with 14 daily injections survived the first and second infective dose. At the end of a year, they were again injected with the third infective dose, and 2 out of 3 survived, showing protection over a period of 1 year.

The results indicate that the previous injections of 0.1 c.c. of live rabies virus

† 5% Brain tissue emulsion rabies virus.

‡ Death preceded by definite symptoms of rabies.

intralingually had no appreciable immunizing value, inasmuch as the 7 dose rabbits died, while the 14 dose rabbits survived the second infective dose.

SUMMARY

The intralingual injection of the infective dose of rabies virus makes it possible to obtain fairly consistent results in the protection test of rabies vaccine on rabbits. The test brings out the greater protective value of a series of injections indicating that 7 doses is the minimum to insure survival of the rabbits infected 14 days later.

CONCLUSIONS

1. Rabies vaccine (chloroform killed)

and rabies vaccine (phenol killed) both passed the protection test in an equally satisfactory manner.

2. Rabies vaccine (phenol killed) kept at room temperature fails to protect when the vaccine is more than 2 years old.

3. Rabies vaccine (phenol killed) kept at room temperature for 2 years satisfactorily passed the protection test, supporting the contention that rabies vaccine can be dated for 2 years from the date of issue.

4. The injection of 14 0.5 c.c. doses of 25 per cent brain tissue rabies vaccine (phenol killed) has been shown to result in protection in rabbits lasting at least 1 year.

Early Diagnosis of Primary Syphilis*

Practical Darkfield Examination by Mail

HEWARD ELLIS ELMER

Heiligenwalde über Königsberg (Pr)5, Germany

THE collecting outfit described below has been used successfully by the writer over a period of 6 months in sending by mail, from the venereal disease clinic to the laboratory, specimens of exudate from chancres and syphilitic condylomata for darkfield examination.

It is found, in confirmation of observations of other workers,^{1, 2} that the *Treponema pallidum*, when properly preserved, will remain motile for at least several days. We find that a re-

inclusion of air with the specimen we either fill the capillary tube completely or else break off the ends of the tube close to the enclosed drop of fluid. We then immerse the tubes entirely in vaseline, contained in a small tin box;

liable diagnosis of syphilis by means of the darkfield microscope may be obtained when the laboratory is as much as a week distant by post from the clinic.

We found the prime essential in preserving the viability of the *Treponema pallidum* to be exclusion of oxygen. We collect our material, simplifying the method of Mahoney and Bryant,¹ in small glass capillary tubes. To avoid

by laying the tube horizontally on the vaseline and gently pressing under the surface. At the laboratory the fluid is expressed on to the microscope slide by pressing one end of the tube into a small block of soft paraffin wax (equal parts of wax and vaseline).

The collecting outfit consists of the following component parts:

1. Half a dozen small glass capillary tubes, $2\frac{1}{2}$ " (6 cm.) in length. The tubes used for dispensing smallpox vaccine are of the desired length and bore; or they may be easily drawn

* Paper founded on original work by the author while in the Venereal Disease Clinic, Chicago, Ill.

from glass tubing. These tubes fill readily when touched repeatedly to the drop of lymph exuding from the sore.

2. A small corked test tube to carry the capillary tubes and serve for return of blood specimen for serologic tests. A round-bottom vial, 7/16" x 3", with fairly heavy wall, stoppered with a No. 3 cork, meets requirements.

3. An oblong tin box with removable cover in the long dimension, 3/4 filled with vaseline. A box described as follows was obtained in a stock size: "plain tin oblong seamless slip-cover box, 2-9/16" x 7/8" base by 1/2" deep." A mixture of vaseline containing 5 per cent paraffin wax is of the proper fluid consistency and of a melting point to withstand summer temperatures in the mail without flowing. One lb. of vaseline is sufficient for about 100 boxes.

4. Two grease-free microscope slides (enclosed in a small envelope). These slides are for air-dried smears from the lesion for staining by Fontana's or other suitable method, to provide a permanent record in the laboratory if desired.

5. Data card, 3" x 5", bearing on the reverse side directions for using the outfit.

6. Mailing tube consisting of inner tin cylinder (diameter 1 1/2", length 3 1/2") and outer cardboard mailing case (diameter 2", length 4").

The method here described for pre-

serving the *Treponema pallidum* in a viable state during transmission by post permits a reliable diagnosis of syphilis when the laboratory is situated at a distance from the clinic. For the practising physician, particularly for the physician in the smaller town, and above all from the point of view of the public health department, this possibility is of the utmost importance in that, as has been shown³ treatment of seronegative primary syphilis is almost 100 per cent successful when instituted within 14 days of the first appearance of the chancre and, as has also been pointed out⁴ any diagnosis of syphilis not confirmed by laboratory findings remains practically always open to question.

Fevers of the Typhoid Group in Members of the Civilian Conservation Corps During 1933

GEORGE F. LULL, M.D., DR.P.H.

*Lieut. Colonel, Medical Corps, U. S. Army, Statistical Sub-division,
Surgeon General's Office, Washington, D. C.*

ON March 31, 1933, the President approved the action of Congress (48 Stat. 22) for the relief of unemployment. As a result, the Civilian Conservation Corps was created and over 200,000 young men were enrolled and sent to small camps throughout the United States.

These men were examined physically and inducted into the Corps by the Army. Army officers supervised their clothing, feeding, and vaccinations, and accompanied them to camps, remaining with them, being in charge of everything except their actual work which was performed under the direction of experienced foresters and woodsmen.

All enrollees were given the regular Army typhoid prophylactic. This consists of three doses of a vaccine containing 750 million typhoid and 250 million paratyphoid "A" organisms per c.c. prepared according to standard technic at the Army Medical School, the first dose being $\frac{1}{2}$ c.c. and the second and third doses 1 c.c. each, administered at intervals of 7 days between doses.

These men were scattered throughout the country in over 1,000 camps, almost entirely in rural areas. In many of these areas typhoid fever was endemic so that the exposure rate was relatively high.

During September and October many

men left the camps upon completion of their 6 months' enrollment period, and new men were enrolled to replace them. The average strength for the 39 weeks of 1933 was 222,967, although it is estimated that approximately 450,000 different men were in the camps at various times during the year.

For the entire group during 1933 there were reported 54 cases of typhoid, 11 cases of paratyphoid "B," and 2 cases of paratyphoid "A." The paratyphoid "A" infections occurred, one in a soldier of the regular Army on duty at a camp in Tennessee, and the other in an enrollee in Georgia who became ill after only a few days in camp and before vaccination was completed. Both recovered.

This incidence gives a rate of 0.32 per 1,000 per annum for typhoid, 0.01 per 1,000 per annum for paratyphoid "A," and 0.07 per 1,000 per annum for paratyphoid "B." Four of the cases of typhoid ended fatally, a mortality rate of 0.02 per 1,000 per annum.

The 11 cases of paratyphoid "B" infections were all in the same company in a camp in Kentucky and were traced to a food handler in a local restaurant who was a carrier; all cases recovered.

A study of the 54 cases of typhoid shows that geographically they were distributed as shown in Table I.

TABLE I

GEOGRAPHICAL DISTRIBUTION OF TYPHOID CASES

Texas	32
Oklahoma	10
New Mexico	6
Louisiana	2
Maine	1
Maryland	1
Illinois	1
California	1

54

Data relative to the lapse of time between vaccination and onset of symptoms show that:

Two men reported at camp with symptoms. One man became ill before vaccination was completed.

Three men developed symptoms less than 15 days after third dose of vaccine.

Seven men developed symptoms between 15 and 30 days following third dose of vaccine.

Forty-one men developed symptoms 30 days or more following vaccination.

Considering the 4 fatal cases—one was taken ill 11 days, one 18 days, one 40 days, and one 67 days following completion of vaccination.

Laboratory findings were positive in relatively few of these cases. In some instances laboratory facilities were not available in the hospitals where the patients were treated. Diagnosis was based, therefore, upon clinical findings only in quite a number of cases. As an example in the para "B" outbreak in Kentucky, organisms were isolated from 3 cases only. However, the 8 other patients ill at the same time had the same train of symptoms, so were considered clinical cases. The examination of the food handler in the restaurant was positive for para "B" type organisms.

Polluted water supplies were regarded as sources of infection in 44 of the 54

cases. Although chlorinated water was supplied in camp and men were instructed to carry canteens when absent at work, there was evidence in these cases that the rules were disobeyed and well and stream water from unauthorized sources was ingested.

The largest outbreak occurred in a company camped at Hamilton, Tex. This company had 29 cases with 1 death. The members of the company worked in the country some distance from the camp, and the source of infection was thought to have been a well which supplied water to a family in which there had been 2 cases of typhoid during the last year. Examination of the water showed a high bacterial count with many *B. coli*. Two members of the family residing here were also found to be carriers.

In the regular Army during 1933 there were 4 cases of typhoid reported from troops within the United States, a rate of 0.04 per 1,000. The rate of the total Army at home and abroad was also 0.04 per 1,000.

If the number of members of the CCC exposed to typhoid (approximately 450,000) rather than the average strength be considered, the rates would be 0.12 per 1,000 for typhoid, 0.004 per 1,000 for para "A," and 0.024 for para "B" with a mortality rate of 0.008 per 1,000.

CONCLUSIONS

Infections with the typhoid group were very low in the CCC during 1933. This is especially true if the number of individuals exposed is considered.

The case fatality rate for typhoid was 7.4 per cent. There were no fatal cases of paratyphoid.

A Semi-Automatic Delivery Pipette

MAJOR F. E. DANIELS, F.A.P.H.A.

Pennsylvania Department of Health, Harrisburg, Pa.

THE pipette described on page 59 of the January 1934 number of the *American Journal of Public Health* is interesting and quite useful. It is rugged but limited to the particular volume for which it is made.

On several occasions the writer has constructed a similar pipette to be used for delivering different quantities by the use of interchangeable measuring reservoirs. These pipettes are somewhat simpler and can be easily constructed in the laboratory by anyone possessing only such skill as a good laboratory technician should have. The only piece necessary to purchase would

be the 4-way stopcock, as all the rest is easy. As commercial 4-way stopcocks have different styles of bored plugs, it is important to see that the plug be quadrant bored as shown.

The two side arms are bent upward and cut off at a convenient length.

The top arm is connected with the reservoir of water or material to be dispensed.

The bottom or delivery arm is cut off and drawn into a nice tip.

The side measuring reservoirs may be made to hold any desired quantities. The writer has used interchangeable vessels for 9 ml. and 99 ml. water

blanks. The shanks slip over the upturned side arms and are adjusted to calibration marks of 0.1 ml. for the proper correction for loss in the sterilizer. A rubber gasket well lubricated with graphite makes a firm connection but allows easy adjustment and removal for change of size.

It is well to mount the pipette on a firm wooden support although local conditions suggest various ways of arrangement. The in-flow may be controlled by a stopcock so that one reservoir fills just as the other empties.

NOTE: The 4-way quadrant bored stopcock can be obtained by special order through the Corning Glass Works, Kimble Glass Company, Eimer and Amend, or Arthur H. Thomas Company.

SEMI-AUTOMATIC PIPETTE

Scarlet Fever Toxin—A Successful Immunizing Agent*

O. B. NESBIT, M.D., AND SUE THOMPSON, M.D.

Board of Education, Gary, Ind.

SUMMARY

AFTER giving 49,165 doses of scarlet fever toxin, 20,278 primary Dick tests, and 12,713 Dick retests in the Gary schools, we have found that scarlet fever immunization as recommended for use by the Scarlet Fever Committee is a safe procedure and that it is a valuable asset to a community as a prophylactic measure.

During the 8 years preceding 1925 when Gary's school census varied from 9,811 to 18,438, there were 26 deaths from scarlet fever among 1,241 cases reported. In the following 8 years, up to the present time, since immunization has been carried on, the school census has varied from 20,472 to 28,032, and there have been 1,147 cases with 13 deaths.

In giving Dick tests it is important that exactly 0.1 c.c. of test material is injected intradermally; that the potency of the material is checked; and that the tests are read from 22 to 24 hours later in clear daylight. If there is a question as to whether the test is negative or positive, it should be considered positive and the child should be given doses.

Some severe but no serious reactions have resulted from the 49,165 doses of scarlet fever toxin. When we consider that in one school center last year, out

of 114 who began doses, 107 finished, we see evidence of the infrequency of severe reactions to doses.

During the past year 2,055 primary Dick tests were given, of which 762, or 35 per cent, were negative. Of 368 who were given the usual 5 doses and given a Dick retest 2 weeks later, 788, or 91 per cent, were negative.

During the past year when we retested 171 who had had the usual 5 doses 5 or more years previously, 139, or 81 per cent, remained negative.

Of the 18,980, the total number of primary Dick tests read during 9 years, 46 per cent have been negative.

Among a group estimated at 10,000 who have completed scarlet fever toxin doses, there have been only 9 persons who had a negative retest who have later been reported with scarlet fever.

CONCLUSIONS

1. The most common error in interpreting Dick tests is to read a slightly positive test as negative. The child should be given the benefit of the doubt, and if the reading is questionable he should be given a series of doses.

2. The reaction to the Dick test in an individual may change. May this be due to the general physical condition of the individual concerned? May it be due to a deficient immunity mechanism? This fact, that it is possible to be immune at one time and not immune at another time, may account

* Summary of paper delivered at a Joint Session of the American Association of School Physicians and the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

for the occurrence of scarlet fever in those who have had a negative Dick test. Errors, or change in Dick tests, may occur from: (1) impotent test material, (2) improper injection of the amount or depth, (3) errors in interpreting tests, (4) change occurring in the person tested that permits him to be negative and change to a positive.

3. The full dosage usually should be given at each injection. In a small percentage of cases it may be advisable to repeat the previous dose if a severe reaction has occurred.

4. Urticarial reactions may usually be prevented by giving 0.25 to 0.5 c.c. of adrenalin with the scarlet fever toxin dose. We do not recommend the administration of adrenalin except to persons likely to have urticaria or to the few who may have a tendency to very severe emesis and prostration following a dose.

5. A Dick retest should be given 2 weeks following the last dose and a 6th dose (80,000 to 100,000 skin test doses) should be given if the retest is positive. If a person who has been given a full series and a 6th dose is later found to be still positive, a second series is advised. If, however, such person is at a later date found to be positive again, we usually do not recommend a third

series; but more doses may be given if desired.

6. Immunity obtained from 5 doses of scarlet fever toxin is apparently comparable in results and duration with the immunity against diphtheria obtained in Gary with 3 doses of diphtheria toxoid, a total of 3 c.c., having an antigenic value of $4\frac{1}{2}$ to 8 units per c.c.

7. Most susceptible persons may be made immune to scarlet fever as evidenced by the Dick reaction.

8. Dick tests should be made at certain intervals on a person, even though he has had a Dick negative test.

9. The Dick test appears to be a reliable means of determining susceptibility or immunity to scarlet fever. Persons who have been tested recently and pronounced negative usually escape the disease. They may be carriers and they may spread infection. Symptoms which lead one to suspect that a person who has been closely associated with a scarlet fever patient is a carrier are the presence of acute abnormal discharges in the nose; inflammation of the mucous membrane of the nose or throat; or a mouth full of carious teeth. The presence of hemolytic streptococcus from cultures made from the nose and throat would be stronger evidence of the person being a carrier.

Integration of Federal, State and Local Agencies *

THE following memorandum has been prepared by the Committee on Federal Relations of the State and Territorial Health Officers and approved by every member thereon:

It is the well considered opinion of the committee that a specific and definite policy of the Federal Government should be formulated for discharge of the responsibility of that element of government in the development and maintenance of local health work. Such policies have been formulated in many other functions of government and express or imply the relationships of the several elements of government, each to the other.

Policies with reference to public health administration in the past have been, in most instances, outgrowths of emergency situations, and this has been especially true of the aid extended by the Federal Government in the development and maintenance of local health service. Quite obviously, the reason for this situation is a failure on the part of the body politic to recognize basic responsibilities for continuing work, and to demand continuing support for the discharge of these responsibilities.

Crystallization of a policy into statutory law will be of material aid in bringing about a more constructive understanding and appreciation of fundamental needs in the protection and promotion of the public health, an understanding that it is not the dramatic emergency which is responsible for the greatest loss in vital resources but the unspectacular and insidious conditions that are constantly at work.

This can best be accomplished through the enactment of special legislation which, in addition to enunciating permanent policy, would definitely fix the amount appropriated on a continuing basis and thus avoid the necessity for defense of the appropriation each year.

With these thoughts in mind, the committee respectfully recommends that an Act incorporating the following expressions of policy be prepared and presented to Congress for the purpose of enabling the U. S. Public Health Service to cooperate with state departments of health in the development and maintenance of local health work:

1. There should be in the Act a declaration of policy stating the reasons for and objectives of the Act similar to the following:

It is recognized that the conservation of vital resources through the protection of human life and human health is a national economic necessity; that throughout the United States there is unnecessary wastage of vital resources; that preventing the spread of epidemic diseases from one state to another is the responsibility of the Federal Government; that the most effective means of preventing the spread of such diseases lies in eradicating, at the source, of the conditions responsible for continuing existence of communicable illness; and that many communities, especially in the rural areas of the country, do not now possess resources sufficient to permit the support of necessary health service without aid from other sources.

Therefore, it is hereby declared to

* Report of the Committee on Federal Relations of the State and Territorial Health Officers.

be the policy of the Congress to promote the development of national, state and local health service of such extent and character as to equalize the opportunities for life and health of all the people of the United States and to make possible the prevention of the inter-state spread of disease in the most effective manner.

Since, in the experience of the health authorities of many states it has been clearly demonstrated that the establishment of permanent full-time local health units constitutes an economical and effective method of providing adequate local health service, it is also declared to be the policy of the Congress to render aid in promoting as a primary objective the further development of local health service by providing financial assistance from the Federal Government in the maintenance of full-time local health units in the several states.

2. Authority to detail officers of the Commissioned Corps and other technical personnel for coöperation with state health departments in promoting and assisting in the administration of this service should be granted specifically, by the statute, to the Surgeon General of the U. S. Public Health Service.

3. The principle of basing grants to states on the development of local units of organization, the grants to include a fixed amount per local unit of government with an additional equalizing differential granted on a per capita basis per local unit of government, should be followed rather than that of allotting flat and per capita grants by states. The U. S. Public Health Service should be authorized to study the varying needs of local governments in coöperation with the states, together with the varying ability of local governments to finance local health service. Based upon such studies the U. S. Public

Health Service should be authorized to promulgate rules and regulations prescribing the amount of aid found to be necessary in varying classes of local units of health organization.

4. The U. S. Public Health Service should be given authority to prescribe by regulation any other conditions including the qualifications of personnel, necessary for the wise and effective expenditure of allotments.

5. Allotments to the states for local units of health organization should not be in excess of 50 per cent of the total budget in the beginning; and within not more than 5 years the county and state should assume not less than 75 per cent of the total costs. It is believed to be sound policy to provide for the continuance of a maximum of 25 per cent of the total budget so long as the need for assistance can be satisfactorily demonstrated.

6.* There should be authority for a continuing appropriation which would provide the sum of \$2,000,000 for the first year, increase at the rate of \$500,000 per annum each subsequent year to a maximum of \$5,000,000 available for the 7th year, and continuance at this rate indefinitely thereafter.

7. The U. S. Public Health Service should be granted authority to allocate a specific percentage of the total appropriation for the administration of the service as a whole and to provide for technical consultant service personnel.

E. L. BISHOP, M.D., *Chairman*

* With approximately 600 county health departments at present in the United States and with approximately 3,000 counties in the country, it is believed that the sums mentioned will be required to provide the assistance necessary for reasonably adequate staffing of existing local units of health organization and an orderly growth in the development of any new full-time units. It is apparent that the appropriation of \$2,000,000 for the initial year would provide an average of \$2,500 per annum for the 600 counties now organized, and for the organization on the same average allotment of 200 additional counties throughout the United States. It is understood, of course, that any part of the \$2,000,000 which might not be used the first year would be returned to the Treasury.

High Lights of the Biennial Nurses' Convention, Washington, D. C.,

April 22-27, 1934

EVA F. MAC DOUGALL, R.N., F.A.P.H.A.

*Director, Bureau of Public Health Nursing, State Division of
Public Health, Indianapolis, Ind.*

THE attendance of 7,900 nurses broke all Biennial records. There was speculation as to why so many could afford to get away in these times. However it must be remembered that there is a membership of over 100,000 in the American Nurses' Association, and then the National Capital in the spring was a drawing card. But one could sense subtler reasons than these for the big attendance—an eager quest for knowledge on the part of the nurses; a feeling that times are changing and that nursing must change with them; that there must be better distribution of nursing services; better organization in nursing; closer planning of nursing organizations with other agencies, both local and national.

THE KEYNOTE OF THE PROGRAM WAS CHANGE

This was evidenced by the following topics for some of the joint sessions "The Changing Order of Today" as it Affects the Economic World; Community Life; The Field of Education; Hospitals; and Nursing.

One of the most inspiring addresses at the Joint Sessions was made by a consulting engineer, David C. Coyle, of Washington, D. C., who said that the RFC was a sedative, that the only new thing in this depression was the spasm of bankruptcy, that the price of

progress is capital loss, that taxes will have to be laid on personal income, that "saving for a rainy day makes it rain all the harder," that services is what civilization is really made of. He predicted that there will be fewer men employed in industry because of labor saving devices, that there will be more leisure for all, that those not employed in industry, not sick, and not on an old age pension will be employed in services. Speaking of nursing particularly, he said "It is just your good luck that the things you have always wanted to do for improving the health and happiness of the people happen to be the things that must be done in order to make the economic system operate."

Enlarging on the word services he said they would include building dams on the tributaries of the Mississippi; building sewage disposal plants; eliminating parasites on society like criminals and gangsters; guarding the health of children to make them easier to look at. There will be more money spent on cultural services. Not all will be engaged in highbrow art—some will be "stage hands." Jobs will be more variegated in the future, making workers more intelligent.

Speaking of what use will be made of the more abundant leisure time, he said most people for the last half million years have had to work desperately

hard to keep alive, and that human beings when freed from hard work do not become lazy—they generally have an outburst of energy.

An official from the Federal Emergency Relief Administration, Aubrey Williams, speaking on *The Changing Order of Today as it Affects the Community*, stated that 3,000 units in FERA were working in 9,000 communities in this country affecting 3 million families and from 20 to 25 millions of people.

There is a great change in the attitude of government in that for the first time it announces its interest in the welfare of its people. The federal government has led the way in this and insisted on the same attitude from the states. The government is also insisting that standards be maintained among its professional workers, and is breaking through provincialism by insisting that the ones giving the best services get the jobs.

DISTRIBUTION OF NURSES

C. Rufus Rorem stated that in 1929 only 9 per cent of the people received private duty nursing care, and in that year half the people receiving this care had salaries of over \$5,000 a year; yet people of all other economic grades have about the same amount or more of illness.

Dr. C.-E. A. Winslow of Yale stated that of all nurses one-tenth are in public health, three-tenths in institutions, and six-tenths in private duty. He feels that public health nursing should be for all classes of patients, that there is a discrepancy between hourly nursing and 8 hour duty nursing. He wonders why one agency in a community cannot be equipped to supply all nurses needed in the home—sort of a combination between a nurses' directory and a visiting nursing service. He feels that the separation between nursing done in the hospital and that furnished the

patient in the home by private duty or public health nurses is too sharp.

OF PUBLIC HEALTH NURSING SIGNIFICANCE

Perhaps the greatest revelation the convention brought the public health nurses was the recognition on the part of all of the growing responsibility of official public health nursing agencies. This was well illustrated by the fact that the new president and new first vice-president of the N.O.P.H.N. are superintendents of nurses in two of our big city health departments. Also by the fact that the U. S. Public Health Service has just put one of our leading public health nurses on its staff as a Consultant, who will have another public health nurse as her assistant to make field studies.

Another general feeling brought out that waxes stronger from year to year is the importance of securing the active interest and support of laymen not only in public health nursing, but also in general nursing education and nurse training.

Mrs. Franklin D. Roosevelt, addressing a joint session, stated that the trend in nursing is from private duty to public health nursing. Another trend is toward more teaching on the part of the nurse "to show us how to live physically so we may be healthier, happier people."

Dr. Royal S. Copeland, Senator from New York, stated he felt it was poor economy for communities to cut down on public health and social work when they were spending billions of dollars to counteract crime. He would have the public health nurse know more about psychology and mental hygiene so she could help the teachers pick out the potential misfits in society, and help the parents and social agencies and physicians in a community to correct wrong tendencies early, if possible. He would have a public health nurse work-

ing in every schoolroom in the country. This is right in line with what Herbert Hoover said, "One good community nurse will save a dozen future policemen."

The report of the N.O.P.H.N. Survey of Public Health Nursing brought other revelations to all groups of public health nurses. It is out in book form now obtainable for \$2.00 from The Commonwealth Fund, New York, or the Book Service of the A.P.H.A. It behooves every public health nurse to read it for, as Katharine Tucker says, "It is the first time in the history of public health nursing in the United States that a study so comprehensive in scope and analytical in method has been made possible."

The School Nursing Section of the N.O.P.H.N. had a spirited round-table session on the "Significance of this Survey Report for School Nurses." As a result, a fine report with resolutions and recommendations was made by the secretary at the final N.O.P.H.N. session, which we hope will have wide distribution and deep study.

MEETING OF STATE ADVISORY NURSES

The convention was extended over one day, April 28, to take in an all day session of this group in the Auditorium of the U. S. Public Health Service. Between 20 and 30 states sent their state advisory nurse or a representative. Others present were 4 members of the N.O.P.H.N. Staff, a public health nurse (who presided), and a physician from the U. S. Public Health Service; the Superintendent of the U. S. Public Health Service Nurse Corps; the Supervisor of Nurses of the Indian Bureau; the National Director of the American Red Cross Public Health Nursing and Home Hygiene Service; and the Director of Public Health Nursing for the Ontario Department of Health of Toronto.

C. E. Waller, M.D., Assistant Surgeon General U. S. Public Health Service, welcomed the nurses and sketched briefly the history of the development of the service. Other topics taken up on the morning program were Personnel Practices; Suggestions for Supervision and Staff Education; Records and Reports as Supervisory Devices; General Relationships; and Relationship of Nursing Agencies to the Medical Profession.

In the afternoon Alma Haupt of the N.O.P.H.N. discussed "What We Have Learned From the Civil Works and Relief Program." Some of her conclusions:

Rules No. 7 recognized nursing care as a legitimate lien on relief funds. An existing public health nursing agency could be used and paid on a visit basis.

Results of CWS Employment of Nurses:

Success in getting many unemployed nurses back to work.

40 states had state advisory committees.

New methods of giving staff education to rural nurses were devised.

Interest in getting public health nursing training was stimulated in many new nurses.

Well planned projects stimulated new interest in communities in public health nursing.

Marion Sheahan, Director of the Bureau of Public Health Nursing, State of New York, outlined the points on a questionnaire that is to be sent to advisory nurses in state health departments to form the basis of a proposed review of these services—a joint project of the Public Health Nursing Section of the A.P.H.A. and the N.O.P.H.N.

With the growing responsibility of state advisory nurses for the development of public health nursing in their state in keeping with the trend of the times, many at this meeting expressed their need to meet annually under the auspices of the U. S. Public Health Service just as the state health commissioners and sanitary engineers do.

RESULTS OF THE ELECTION

National Organization for Public Health Nursing.

President, Amelia Grant, New York, N. Y.

First Vice-President, Grace Ross, Detroit, Mich.

Second Vice-President, Mrs. C.-E. A. Winslow, New Haven, Conn.

Treasurer, Michael Davis, Chicago, Ill.

Board of Directors—Non-Nurse Members, William Draper, M.D., Richmond, Va.; Estella Ford Warner, M.D., Washington, D. C.; Alfred E. Shipley, M.D., Brooklyn, N. Y.; Mrs. James K. Watkins, Detroit, Mich.

Nurse Members, Mrs. Anne L. Hansen, Buffalo, N. Y.; Katherine Faville, Cleveland, Ohio; Sophie C. Nelson, Boston, Mass.; Agnes Talcott, Los Angeles, Calif.

American Nurses' Association

President, Susan C. Francies, Philadelphia, Pa.

First Vice-President, Julia C. Stimson, Washington, D. C.

Second Vice-President, Mabel Dunlap, Moline, Ill.

Secretary, Helen Teal, Indianapolis, Ind.

Treasurer, Emma M. Nichols, West Roxbury, Mass.

Directors, Elnora Thomson, Portland, Ore.; Katherine Densford, Minneapolis, Minn.; Genevieve Clifford, Syracuse, N. Y.

National League of Nursing Education

President, Effie J. Taylor, New Haven, Conn.

Second Vice-President, Julia C. Tebo, New Orleans, La.

Treasurer, Marian Rottman, New York, N. Y.

Directors, Elizabeth Burgess, New York, N. Y.; Elsie M. Lawlor, Baltimore, Md.; Edna Newman, Chicago, Ill.; Dorothy Rodgers, Galveston, Tex.

FEDERAL EMERGENCY RELIEF AND PUBLIC HEALTH

FOR some time we have had in mind giving to our readers a clear statement of what the CWA, FERA, CCC and other emergency relief agencies have been doing for public health. All have seen items from time to time from one state or locality or another, but nothing has come out giving collective statistics. After trying various leads, a letter was addressed to the Federal Emergency Relief Administrator. This was replied to by the Director of Public Relations, and the statement was made that, owing to the fact that the CWA endeavor was put into effect almost over night, using machinery of federal, state and local agencies already established, as well as new administrative bodies formed for the purpose, and because the whole movement went forward at such a tremendous pace, it had been impossible so far to collect correct statistics for all the states and from all the bodies which have been engaged in this work. The pressure of relief work as well as the necessity for speed was great. It has seemed worth while to give what we have been able to find out. We are open to both correction and amplification.

Among the projects adopted, we find "Classification G. Sanitation," under which sanitary and storm sewers were constructed, ditching and cleaning of creeks, with the filling in of low places were carried out; sewage disposal, incinerator plants and sanitary privies, septic tanks, etc., were constructed. Under "Classification H. Waterways and Water Supply," come a number of projects which influence public health directly. "Classification F. Pest Control" includes mosquitoes, drainage, oiling and stream clearing.

Under the CWA projects, No. I relates to those benefitting public health. Under this heading come typhus fever control, for which \$1,143,000 was appropriated; spotted fever control, \$79,500; malaria and filariasis control and sanitation, \$312,046; malaria control, \$4,500,000; rural sanitation, \$5,000,000, and the sealing of mines, \$1,519,750. On these projects it was estimated that some

53,000 men were employed. On March 31, the CWA, as such, went out of business and the uncompleted projects under it, including public health, are being continued under the Works Division of the FERA.

The projects including Malaria Control, Rural Sanitation and Sealing of Mines were carried on under the auspices of the Public Health Service, which also took part in Spotted Fever and Typhus Fever Control. The Administrator believes that in a few months (136 days) more has been accomplished for the control of malaria than has been possible in 25 years under the restriction of budget necessary in the Public Health Service. Some 30,000 men were put to work draining and cleaning up breeding places of the mosquitoes.

Some 32,000 men were employed in improving sanitary conditions in rural districts, largely in the South. A large number of sanitary privies have been constructed and the educational value of the demonstration given in proper disposal of excreta has undoubtedly reached a very large number of persons and will do good to many for a number of years, and it is to be hoped, permanently.

The sealing of abandoned mines is being carried out chiefly in Pennsylvania, West Virginia, Kentucky, and Ohio, since discharges from them are changing certain streams from an alkaline reaction to an acid, rendering the treatment of this water for drinking purposes difficult.

We have already run an editorial written by Colonel W. M. Bispham, Medical Corps, U.S.A., on the work of the CCC camps. Although not listed as a measure for promotion of public health, there must be mentioned the expenditure of \$100,000,000 on slum clearance and modern inexpensive housing under the Public Works Emergency Housing Corporation. This must exercise a wide-reaching effect on health.

Apart from the work which has a direct public health value, the fact that approximately one billion dollars, according to the estimate of the Administrator, has been spent, 750 million of which was for labor and the remainder for material, has necessarily had a good effect on public health generally. The maximum payroll has been as high as 60 million dollars a week. In the United States during October and November, some 14,600,000 people were receiving unemployment relief.¹

A limited amount of observation indicates that the people receiving relief spent the money given to them wisely, and the same is true of the CWA workers. Of those receiving relief in January, 1934, 42 per cent were children under 16 years of age, with 36 per cent of preschool age.²

Needless to say, in an enormous project gotten up and put through at such a tremendous speed, there has been some graft and some foolish expenditure, as well as waste. A striking instance of this is the assignment to a man holding the degree of B.S. in Agriculture (incidentally, the most appropriate degree that any university gives) to make a study of poliomyelitis. It is not clear just what conclusions were reached, but we are led to believe that it is probably dangerous to let concrete come in contact with drinking water! Nearly 20 pages of foolscap were wasted on this wonderful paper, entitled, "What is Poliomyelitis? Is not Its Infective Agent a Micro-inorganism?" However, in spite of some drawbacks, there is no question that much good work has been done, and it is greatly to be hoped that permanent results have been achieved.

WILLIAM HENRY WELCH

THE death of Dr. Welch, who reached his 84th birthday on April 8, 1934, removes from the medical world a notable figure. He had been suffering from cancer of the prostate and had been practically confined to the hospital for more than a year.

Dr. Welch and the late T. Mitchell Prudden shared the honor of being the American pioneers in renouncing medical practice and devoting themselves wholly to teaching and investigation in pathology. "Finally there appeared on the horizon in this country a few anomalous individuals who cherished the notion that the science of disease, even in its etiological and morphological aspects alone, was broad and deep enough to command the exclusive attention of its devotees" (Prudden¹).

Dr. Welch was among the first to take up and teach the new science of bacteriology in this country, after having returned from some four years of study in various schools in Continental Europe—Breslau, Strassburg, Leipzig, Vienna, and Berlin. He held the chair of Pathology at Bellevue Hospital Medical College, New York, from 1879 to 1884, when he moved to Baltimore as Professor of Pathology of the Johns Hopkins Medical School, a position he held until 1916, when he became Director of the School of Public Health in the same institution. From 1893 to 1898 he was Dean of the medical faculty there and was one of the original four in the Medical School, the others being Drs. William Osler, William S. Halsted, and Howard A. Kelly, the last being the only surviving member of the group.

Dr. Welch's interest in bacteriology was always great and it was natural that he should develop great interest in public health, which constantly grew and culminated in the establishment of the School of Public Health, of which he was the first Director, and the funds for which were obtained through his influence.

He was one of the first to see the importance of the antituberculosis movement in this country, was active in the formation of the National Tuberculosis Association, and became its President in 1910.

He has been connected with the Rockefeller Institute, of New York, and the International Health Board since their foundation, and has had great influence in determining donations of Mr. Rockefeller to the advancement of public health, and medical education. Since 1901 he has been President of the Board of Directors of the Rockefeller Institute.

It is to be regretted that Dr. Welch did not embody his experiences in a volume, though numerous addresses have been collected by his friends. He was born just before Pasteur began to publish the story of his discoveries. He saw the birth of the so-called germ theory of disease, its rise, and its proof, and witnessed the isolation of all the pathogenic organisms, both vegetable and animal, now known to us. Truly he lived through the most remarkable period of the world's history, and a chronicle from his facile pen would have been invaluable.

Perhaps no scientific man who has ever lived had as many honors as Dr. Welch. From every part of the world came degrees and titles. He was a facile speaker, always charming and always carrying his audience with him.

His personality was delightful. He was approachable, genial, interesting, a friend of young men, and ready to give credit to every beginner. He has probably done more to stimulate work and encourage scientific men than any other teacher in America. Apart from his teaching, he was interested in all public

health movements, serving on boards and engaging in many other activities for the public good. He was President of the State Board of Health of Maryland from 1896 to 1922. He was a charming host, and delighted in entertaining distinguished men who visited this country, but always included among his guests not only those closely connected with him in his work, but other young scientists who might be available.

His life has been a striking example of devotion to science for science's sake. Commercialized, his salary could have been easily more than a hundred thousand dollars annually; yet for practically all his life, it was only the modest stipend of a professor.

During the World War he was one of the first to go into the service of the country in 1917, as a Major in the Medical Corps, being advanced in 1918 to the grade of Colonel. He spent much of his time in Washington, where his advice to the Medical Department of the Army was invaluable. The soldiers who were engaged in the World War owe much to his wise counsel for the care taken of them.

He has been a member of the Laboratory Section of the Association since 1917, and was made a Charter Fellow in 1923. The Association as a whole mourns his loss and pays tribute to his memory.

THE MEDICAL EXAMINATION OF FOOD HANDLERS

THE outbreak of amebic dysentery in the City of Chicago in the summer of 1933 has excited unusual interest. Nothing was published about it until October 9, when a paper was read before our Laboratory Section at Indianapolis. Cases have been traced to more than 200 cities, including some in Canada, which had their origin in Chicago. The Public Health Service was called on and two news letters were sent out regarding it. In February, an article on the subject appeared in the *Public Health Reports*.¹ It is known that carriers of the *Endameba histolytica* are found fairly commonly, and one great question which comes up for discussion is the advisability of examining food handlers. On this there is diversity of opinion. Some health officers believe it to be ineffective and that the expense is not warranted by the results. Extravagant statements are made against it by some, one former health commissioner going so far as to call it a "worn out superstition of public health."

In the article referred to there is a good deal about the examination of food handlers, especially in regard to those carrying amebae. The tone is negative, and every possible difficulty and objection is pointed out. The author speaks of the inadequacy of methods, the number of examinations necessary to give a conclusive answer, the intermittency of the carrier condition, the time, effort and expense involved, and the difficulty of controlling carriers when detected. The danger of carriers is recognized. The opinions of the two schools of protozoologists are spoken of. The difficulty of, and errors in, diagnosis are mentioned, but do not seem to be a good reason for not trying to prevent the ailments from which those infected suffer. Finally, the author states that even a positive report will be misleading, since a cyst carrier may be suffering from a condition not related to the presence of the protozoa. In the face of conditions which exist, we

believe that the positive and not the negative side of the question should be taken.

We cannot but recall the outbreak² on the Steamship "Rochester" in 1913—300 passengers; 235 traced; 122 cases of gastroenteritis, 42 cases typhoid-like; 5 deaths. Cause—a meat cook with profuse diarrhea in febrile stage of typhoid. We remember also Typhoid Mary, who according to the last accounts which we have, has been the cause of 57 cases of typhoid fever, with 3 deaths, and there are some who believe that she was responsible for the infection of water which caused the epidemic in Ithaca, N. Y., in 1903. We also recall the case of "H.O." who though not a food handler, infected the water supply of a ship by using the common water supply. In regard to all of these cases, we would ask whether or not the examination of food handlers would have been worth while?

There is no doubt that the examination for amebae offers greater difficulties than does the examination for bacteria, and there is recent evidence that carriers do not play as important a part as they do in bacterial diseases, but the general principle remains unchanged. A recent survey of 2,000 food handlers in New York City³ shows a total of 35 cases of latent adult tuberculosis, and 46 cases of active pulmonary tuberculosis. Can the employment of people with active pulmonary tuberculosis in such callings be justified? Can they be detected without examination?

As to the carrier condition, we know of no better statement than that made by the late Dr. Henry J. Nichols.⁴ The article under discussion indicates that there is nothing to do with food handlers except to educate them in personal hygiene, which all recognize would be a valuable means of prevention, but the question is raised as to whether they can be made sufficiently conscious of the menace to make this measure effective. Dr. Nichols says that carriers may be instructed in personal hygiene, but that if they do not respond to social obligations, restrictive measures must be applied. In the instance of Chicago, in spite of the recent report of the special committee, it would have paid handsomely to have had an officer stationed in the toilet rooms to enforce observance of the rules laid down by the committee.

On the question of the results justifying the expense and trouble, Nichols points out that "as scientific knowledge increases, there is an increasing demand for its application in the amelioration of human life." In regard to the difficulties on the administrative side, he says: "But one point should be kept clear. The interests of the group of [or] race are supreme over those of the individual. This decision has been handed down by Nature and by Society and other decisions must conform."

We have recently spoken of the movement in New York City, where a committee is urging the public to demand cleanliness in eating places. This movement will be carried out largely through education of the public. While the public may be apathetic in many cases, there is no question that when there is proper education there is a growing demand for the application of scientific facts to public health.

The article also questions the advisability of treating all food handlers with amebicides in the present state of our knowledge, though recognizing the necessity of treatment of recognized clinical cases, even though mild.

From the scientific standpoint there is perhaps nothing in this article which can be found fault with, but published in the official organ of the Service, we believe it is liable to do a great deal of harm. Similar difficulties have confronted

us in the control of all contagious diseases, and if we had sat with our hands in our laps looking only at the difficulties and not for means of overcoming them, we would be in a sorry condition today, whereas the advances we have made constitute one of the great features of which the medical profession has good reason to be proud. We look for leadership in progressive measures for the protection of health, rather than a negative attitude or a recital of difficulties.

LETTER FROM GREAT BRITAIN

THE DROUGHT, THE WATER SUPPLY,
AND DISEASE

The description of the British climate alleged to have been applied by a visiting American as, in fact, no climate at all but merely a series of samples, is one that the average Briton accepts as at once witty and accurate. Variability is undoubtedly one of the characteristics of the weather, the variations commonly suffered including as a rule a rather generous allowance of rain.

Up till the last 12 months or so, at any rate, this seems to have been the case. During that period, however, the variability has taken the direction of an omission of rainfall, and as a result the members of the population, considerable in number, whose entire subject of conversation is the weather, having to take a new line, find it less easy to maintain an even flow than in the days when the drip of falling water was there to provide an accompaniment.

The absence of conversational openings, the result of the drought, is, of course, most noticeable in the urban areas where precautions have been taken to guard against shortage of supply. In rural and outlying districts the situation is different, and in government and official circles the view taken steadily becomes more serious, and very real efforts have been, and are being, made in order to assist in securing and increasing supplies.

So far as the taking of serious views is concerned, the lay press has tried very hard to be helpful by indicating the terrible things that are happening, and predicting that though results even more terrible will occur if the drought continues, those that will ensue upon its termination will be catastrophic. Most of the effects, it is hardly necessary to say, are or will be upon the health of the people. The prevalence of infectious disease, in particular, the press believes to be certain to be affected.

Curiously enough, in spite of all journalistic effort, there has been little evidence of increase in the amount of infectious disease generally throughout the country. In some areas the number of cases of measles has been greater than in 1933, but this had been anticipated, and is in accordance with the character of this disease and the normal course of events. Scarlet fever in certain places has also been slightly more prevalent, but the rise here again is the ordinary periodic one. The fact that there appears to be an increase in the number of adults who have contracted this infection is one that has been the subject of mention. The explanation suggested for this is, of course, that as a result of the reduction in the amount and virulence of the disease during recent times, numbers of persons escaped infection in childhood, or if

they acquired it, had conferred only a transient and very minor degree of immunity.

So far as can be made out there has been no exceptional prevalence either general or local of enteric fever or intestinal complaints, though, as the press has suggested, this may appear when the drought really breaks and there comes the heavy and prolonged fall of rain that so many so very ardently desire.

THE SEASON OF CONFERENCES DRAWS NEAR

In spite of the drought, the slum clearance drive and everything else, preparations go steadily ahead for the various congresses and conferences that are held annually during the summer and early autumn months. Most prominently, of course, is the health congress of the Royal Sanitary Institute, which is fixed for July 9-14.

The venue on this occasion is Bristol, a city attractive of itself, historically and otherwise, and set in most pleasant surroundings. Recently it has come into prominence in public health circles on account of the setting up within the university of a department specifically concerned with preventive medicine and the carrying out of works of this type on behalf of the city, the main connecting link between the university and the municipality being the Medical Officer of Health (Dr. R. H. Parry) who has been appointed to the chair of preventive medicine.

The arrangements so far as the health congress is concerned are largely on the lines followed at the American Public Health Association conference, questions being grouped for discussion at appropriate sections or meetings of specialist officers. Housing and slum clearance being, as I have mentioned in previous letters, very much to the fore at the moment, will receive a great deal of attention, and the Minister of Health himself (Sir E. Hilton Young), no less,

has promised to attend and address the congress on some aspect of the housing problem.

Another matter exercising many minds at present is the problem of mental deficiency. This is to be discussed at a joint meeting of the preventive medicine section and the conference of medical officers of health.

LINKS WITH THE A.P.H.A.

The President of the Society of Medical Officers of Health (the individual who signs this letter) will preside over the meeting, and will have the support of, among others, Professor W. W. Jameson of the London School of Hygiene. Professor Jameson has only recently returned from a visit to India and the East, made at the instance of the Rockefeller Foundation, along with Dr. F. F. Russell, the Director. A further claim to particular distinction possessed by Professor Jameson is that he is the junior member of the small but very proud group of Honorary Fellows of the American Public Health Association in this country.

Talking of honorary fellowships, perhaps I might be permitted to refer to the great pleasure it gave me to be present at the meeting of the Royal Sanitary Institute when Professor Haven Emerson was elected an Honorary Fellow of that body. The honor of fellowship, such as it is, I am certain has never been more worthily conferred than in the case of Dr. Emerson, nor have I known a proposal that it should be offered received with greater warmth.

CHILD WELFARE AND TUBERCULOSIS

To return to the subject of conferences and congresses, I may note as a matter of interest that the usual annual conference on maternity and child welfare this year is to be held during National Baby Week in Birmingham from July 3 to 5. The

main subject for discussion is the causation of neonatal deaths. A report on the measures taken to reduce neonatal mortality and the results so far achieved is to be presented by Dr. G. F. McCleary. Dr. McCleary, who was formerly a Medical Officer of the Ministry of Health on the national health insurance side, has many friends in the United States, having visited and also, I understand, lectured on insurance questions in a number of medical schools and universities.

Other matters down for discussion at the conference are orthopedic work among preschool children; the new approach to social work, and the solution of nutritional problems. The maternity and child welfare group of the Society of Medical Officers of Health holds one session at the conference for

the purpose of discussing the prevention of tuberculosis in the child under 5.

For the more general consideration of questions relating to tuberculosis the National Association for the Prevention of Tuberculosis is to hold its annual conference—the twentieth of the series—in London on June 14 and 15. The conference is to take the form of an all-round discussion upon the experiences gained during the last 21 years as a result of the operation of the national tuberculosis scheme. Since the conference is to be in London, it may be anticipated that the gathering will be a particularly brilliant and representative one, and that contributions of great moment will be made to the discussion: even, perhaps, something in the nature of “pronouncements.”

London CHARLES PORTER, M.D.

EDUCATION AND PUBLICITY*

WHAT HEALTH EDUCATION IS

Public health education may be broadly defined as the act of making health information public by technics which arouse, stimulate, and guide motives for healthy living. It is the imparting of knowledge whereby the individual may understand what is his birthright in terms of health and longevity, and gain information of methods and facilities for preserving this birthright.

—Ira V. Hiscock in *Transactions of National Tuberculosis Association*, 1933.

More about Syracuse—In the March and April, 1934, issues we suggested the interest and value in the reports by Professor Winslow and Miss Bache on adult health education during the Syracuse Demonstration.

We also called attention to the absence from both reports of information as to the basis of a health education program.

The following from Dr. George C. Ruhland states very clearly the thought of the Commissioner of Health during the Syracuse Demonstration:

I feel that it is not quite just to Syracuse to say that the health program there proceeded without thought of the philosophy of health education and a program. Possibly we disagree with regard to what is meant by a philosophy or a program. So far as the Syracuse Health Demonstration is concerned, the program devoted its health educational work to the stimulation and promotion of a popular interest in recognized branches of public health activity. I do not conceive a program in public health as the promotion of only one major objective to the exclusion of other health needs—as—for example—to stimulate the building of a hospital or the establishment of special (tuberculosis) clinics. While these may be major objectives in a given health program, they manifestly cannot monopolize

the publicity so far as this is sought through the public press.

In fact, it is my philosophy that public health education must recognize that variation of the theme is most important if public interest is to be held—quite apart from the fact that papers will not be interested to publish stories on the same theme week after week and month after month. We must be opportunists in the publicity that we solicit for health education. I think you will get what I mean if you will ask yourself the question: "What should have been the program for Syracuse?"

The very fact that the Demonstration was conceived to apply all that was known and found worth while in public health practice made it of necessity a program with multiple features.

Questions about Adult Health Education—Some questions raised by Professor Ira V. Hiscock about health education addressed to adults:

Has our program been planned so that it will not be spread too thin in the effort to reach the whole public? Has the emphasis been properly placed as to subjects, and to groups to be reached? Have we featured health in too general terms and failed to stress specific topics? Have we used the most effective technics? Have we sufficiently tested our methods on a small scale before attempting an extensive mass education project? While we may not be able to answer all of these questions in this session, it would seem desirable that we periodically take account of stock, and consider more fully some

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

of the problems and the possible returns from the energy and funds expended in the name of public health education. . . .

Public health education should keep abreast of science, but never overstep the principles which have been established. Health facts can be presented clearly through simple words and obvious and attractive illustrations. Chief among the channels of instruction, to be later discussed, are newspapers, bulletins, folders, pamphlets, magazines, radio talks, motion pictures, exhibits, posters, and public addresses. These instruments, properly used, are all of assistance in their twofold object of securing popular support for the community health program, and of bringing into contact with physicians and other professional personnel the individuals who are in need of their services. "Mass methods of this kind form, however, only a first step toward the goal which is in view. Education in hygiene is after all a very personal matter. The kingdom of health, like the Kingdom of God, is within you" (Winslow). The personal contacts of the public health nurse and of other health workers, in many respects, constitute our most effective means of health education.

"The Philosophy of Health Education," *Transactions of National Tuberculosis Assn.*, 1933.

Honolulu Reports—From Hawaii comes one of the most interesting and effective of health agency annual reports. "Palama Settlement's 38th Year of Concern for Honolulu's Needful." Note the italicized phrase. An aerial map of a section of Honolulu covers most of the two cover pages with an unobtrusive insert of the Settlement buildings and an arrow pointing to their exact location. The title fills the space above the skyline of mountains at the top of the aerial view.

The contents are well selected, well laid out, and the story is told in terms of human beings rather than abstract phrases.

The open pages seem just right for the combined silhouette-outline sketches. The Wortman cartoon, a clinic interior from *New York World-Telegram* is available for use by any health agency. The 6 by 9½ inch envelope is given

distinction by broad bands of blue (about 2 inches wide) across each end in which "Palama Settlement" and "For the Promotion of Public Health and Social Welfare" appear in white letters.

"Aloha!" to Dr. Philip S. Platt, also the printer, and others who may be concerned.

Again "Yellow Jack"—Says Leon Whipple in *Survey Graphic* (May, 1934. 112 East 19th St., New York, N. Y.) about the play now being shown on Broadway:

Yellow Jack is not propaganda unless to inspire us in the ancient war of Man against Death. It is a significant experiment in translating to the stage a great moment in race history—the conquest of yellow fever in Cuba in 1900 by Dr. Walter Reed and his heroic colleagues of the Yellow Fever Commission. It is a success for with the simplest devices of stage levels and spot-lighting, it makes vivid and comprehensible this struggle of science and human courage, to audiences so absorbed that they do not notice there is no intermission. Here is one of the great forces of modern life, in shirtsleeves, gambling with death, the villain a tiny mosquito. Graphic scenes of emotion, humor, laboratory ritual unroll new understanding of how old and new schools clash, how doctors and plain men sacrifice life for other lives, what spiritual force it takes to ask such sacrifices, how the triumphs of science are mingled of the fanatic hunches of a Scotch Dr. Finley, the inspired imagination of a Walter Reed, the precise experiments of martyrs like Lazear.

Two Main Lines—The seventh annual report of Bellevue-Yorkville Health Demonstration says:

Broadly speaking, there are two main health educational methods which can be employed in acquainting the public with the teachings of preventive medicine, and in influencing them to seek medical advice and treatment. The physician, the teacher, the public health and clinic nurse, and the social worker—all these can do and are doing constructive and most effective work in the field of public health education. The work of these special agents can be supplemented by

a general campaign to popularize health knowledge through literature, meetings, radio talks, exhibits, newspaper, publicity, etc.

Public health education in the field of preventive medicine has generally employed both methods. A review of health educational campaigns would show that it was necessary to prepare for this work those who come in direct contact with the general public and, on the other hand, that it was important to carry on campaigns on a large scale by the written word in order to solidify these efforts and awaken the community to its responsibilities; for measures of prevention and control of preventable diseases have only succeeded as rapidly as public opinion was ready to support these measures, and general campaigns have helped to prepare public opinion for this.

Four pages in the 1933 mimeographed report outline the major campaigns carried on in 1933 and the publications issued. Bellevue-Yorkville Health Demonstration, 325 E. 38th St., New York, N. Y.

"Humanizing Education through Dramatization"—Under this title we are told that

Dramatics are the natural expression avenue of activity on the part of pupils. Humanized education through dramatization seeks to build around the child's instincts, impulses, and interests, and enrich his experiences through the interpretation of emotions. . . .

The aims and objectives of dramatization are divided into two classifications, information and entertainment. Each has its contribution to make to the curricular and extra-curricular activities of the school.

A swift survey of the types of the plays, pageants, and puppet shows reveals numerous published productions on the market. While these are elaborate in design and colorful in conduct, they definitely lack in the creative contribution an original performance by pupils has. . . .

The informal play given spontaneously makes a valuable contribution in vitalizing and humanizing the curricula. Here the teacher acts as a guide, encouraging and assisting. The responsibility and initiative rest with the group. The children select scenes, choose characters, and arrange equipment. The characters converse impromptu and gesture and move impulsively. The success of this type of dramatic activity will depend some-

what upon the child's experience and background in the pantomime, portrayal of moods, character sketch, and the tableau. An informal play affords excellent opportunity for coöperative group work. It stimulates interest in writing original plays.

The authors discuss briefly various dramatic forms: formal plays, pantomime, character sketch, tableau, pageant, puppet and marionette, and call attention to both disadvantages and advantages of the play medium for use with children. The emphasis is upon pupil-planning, but they grant that

Formal plays written for children have a place in the educational program. Their reproduction affects a form of study which may be correlated effectively with the subject matter studied. Such selected plays should be carefully considered in light of the richness of content and opportunities for forming correct concepts.

—by G. W. and N. D. Wright. *Educational Screen*, 64 E. Lake St., Chicago, Ill. April, 1934. 25 cents.

Health Education as in Boston—Author C. V. Wilinsky has sent us a copy of *The Health Units of Boston, a report for 1924-1933 of the health centers conducted by the Boston Health Department, but financed by a private fund. The health education chapter says:*

In the sense in which it is used in a health department "health education" means procedures that teach to the community ways of gaining and maintaining good health. As the economic conditions of a community become more and more a problem, the work of the health educator becomes a more vital factor. If the health standards of the city are to be maintained, if maternal and infant deaths are to be reduced, if there are to be fewer deaths and cases of communicable diseases, if the degenerative diseases are to be kept under control, health education must be carried on. People must be taught how to make the best possible use of the limited means available to them. They must be taught how to spend their money in a way that will keep them in good physical condition; to spend it so that their children will not suffer markedly from malnutrition. They must be taught how to

make their homes conducive to healthy living, in spite of the fact that, many times, more than one family must live in a small tenement. They must be taught scientific methods of preventing certain diseases and given instruction on healthful living in general.

How Boston makes the application is outlined in the report.

Value of Health Propaganda—Recently a session of the Section of Medical Sociology, British Medical Association, was devoted to this subject. Three papers, written from the point of view of (1) the administrator, (2) the practitioner, and (3) the press, "had been circulated beforehand among the speakers invited to join in this discussion."

The opponents of health propaganda appeared to object to it most strongly because it "accentuates that morbid absorption in his, or her, own health on the part of individuals, which is one of the worst vices of our time." Another speaker said that "To teach healthy habits to the young was valuable, but to make the young think about their health implied failure." And another warned against making hypochondriacs. There are several supporters of the belief that health services and treatment are in themselves adequate methods of spreading health knowledge.

Those who approved of propaganda argued on the ground of changed attitude of parents toward school medical service, the need for overcoming suspicion of employees toward the idea of periodic medical examination, and the necessity of keeping the public in touch with the progress of medical science. There is general approval of the use of the press.

"With Our Contributors"—Do we make the most of the personalities and the background of the contributors to professional and popular health

journals? Various general and special magazines give interesting notes about their contributors. They, too, usually bury such material where it must be searched for. What seems the better practice is that adopted by *Saturday Review of Literature*, New York, N. Y. Here the notes follow the articles in the form of a brief paragraph printed in italics.

Understanding The Child, Massachusetts Society For Mental Hygiene, Boston, Mass., is an example of a health periodical providing information about its contributors. But one must turn each time to a back page to learn about the author of an article.

"Contents" versus "Index"—The generally accepted form and location of the index and the table of contents is not followed in a number of public health reports. The customary use is to place "contents" at the front, and "index" at the back. The table of contents is a list in the order of appearance; the index is the indication, more detailed than the contents, under whatever classification in abc order will make it easily possible for the reader to locate whatever material he is looking for. Reports and other publications will be more usable and therefore more useful as these forms are followed.

A New Title for an Old Job—"Consultants in Social Work Interpretation" has replaced the exhibit division of the Department of Surveys and Exhibits as the covering title for the work of Evart G. and Mary Swain Routzahn, staff members of the Russell Sage Foundation. This is a change in name only and does not affect the nature of the work done. The exhibit, earlier recognized as an important tool for public education, has for some time been absorbed into the broader field of educational publicity in the Depart-

ment's studies. The exhibit division was originally started at the request of a group of national health and welfare agencies, and the broadening of the work was in response to the rapid evolution of education and publicity in all of those fields.

Fifty West Fiftieth Street—This address is now to be substituted for 450 7th Avenue which has been given here so many times for various national health agencies which have been housed for so long in one office building.

Popular Books on Health—"Books Of General Interest For Today's Readers"—has been

. . . prepared to meet the demand for a list of simply written, informative, and readable books suitable for use in connection with the current adult educational activities being conducted by the government and other agencies. . . . The widespread distribution of this list has been made possible by the generosity of the General Education Board.

Under "Health" are listed: "The Care and Feeding of Adults," by Clendenning; "Our Common Enemy: Colds," by editors of *Fortune*; "Yourself and Your Body," by Grenfell; "Eat, Drink and Be Healthy," by Lieb; "Diet and Health," by Peters; "Health Through the Ages," by Winslow and Hallock; "Family Food Supply," and "Three Meals A Day," Metropolitan Life Insurance Company.

Copies from American Library Assn., 520 N. Michigan Ave., Chicago, Ill. 25 cents.

What do you think of this list for its stated purpose? Would your list vary from the above?

SCHOOLS AND CHILDREN

"Light and Shade" is a chart to accompany "Health Through the Ages," both issued by Metropolitan Life Insurance Co., New York, N. Y. A picture record from "Prehistoric

Times: The Ages of Fear" down to the "Period of Rapid Scientific Advance."

Yellow area represents the gradual progress man has made in acquiring and applying scientific knowledge, in advancing health, and lengthening life.

Blue area represents gradual decrease in superstition, in reliance on magic and incantation, and in guesswork in dealing with problems of sickness and health.

"Health Instruction in Grades IX-XII," by J. F. Rogers, M.D., Office of Education. 22 pages. Supt. of Documents, Washington, D. C. 5 cents. A readable review of "the struggle of hygiene for a place in the high-school program," and the present status of health instruction.

The tentative list of topics for *Health Bulletin for Teachers*, 1933-1934. Metropolitan Life Insurance Co. *Free*. Sept., You and Your Community; Oct., The Water We Use; Nov., The Wastes of the City; Dec., Your Milk Supply; Jan., Your Food and Your Drugs; Feb., Working Together to Control Germ Diseases; March, The Health of the Child; April, The Health of the Teacher; May, The Doctor, the Dentist, and the Nurse; June, The Year's Progress in Health.

LEST WE OVERLOOK

Statistical Bulletin, Metropolitan Life Insurance Co., New York. Monthly review of varied health statistical data. *Free* to health and social workers, physicians, economists, statisticians, actuaries, editors, and libraries.

"Health," a department in *The Survey*, 112 East 19th St., New York. A midmonthly department on public health for social workers edited by Mary Ross. \$3.00 per year. Sample *free*.

EDUCATION AND REFERENCE

The most usable and easily available set of examples of diverse types of charts and diagrams is supplied upon

request by Merwin-Davis, 144 E. 86th St., New York, N. Y. There are 7 sheets, 8½ by 11 inches, carrying classified examples: bar and column charts, line and surface charts, circle diagrams, decorative charts, miscellaneous charts, maps, uses for charts. "Bar and Column Charts" includes 24 examples, including 4 samples of spacing.

When they were first issued in 1933 we overlooked an exceptional series of sex education booklets issued by American Medical Assn., 535 N. Dearborn St., Chicago, Ill. Written by Thurman B. Rice, M.D., the titles make clear the contents to which engraver and printer have given an attractive setting: "The Story of Life for Boys and Girls of Ten Years"; "In Training—for Boys of High School Age"; "High Life Goes On and On—for Girls of High School Age"; "The Age of Romance"; "The Venereal Diseases." 25 cents; set for \$2.00.

"Mass Education," by Bertrand Brown. Milbank Memorial Fund, 40 Wall St., New York, N. Y. 30 pages. 25 cents. Reprint from *Quarterly Bulletin* of the Fund. Reviews the main elements in mass education, and their use in adult health education. *Only a few copies left.*

"American Vitality Maintained in 1933" is treated in *Statistical Bulletin*, Metropolitan Life Insurance Co., New York, N. Y. Jan., 1934. *Free.*

Nursing service anywhere, of any type, under any auspices may use to advantage illustrative material offered by N.O.P.H.N., 50 West 50th St., New York, N. Y. A poster on paper (20 cents) or on card with easel back (30 cents), 14 by 24 inches. Less 5 cents each for 12 or more. Four half-tones, 2¾ by 3½ inches, each \$2.50, or glossy prints 7½ by 9½ inches, same subjects, 50 cents each. Ask for illustrated folder.

"Maternal Mortality in New York City," by Ransom S. Hooker, M.D. Abstract of the report which attracted

so much attention. Reprint from *Health Examiner*. New York Academy of Medicine, 2 E. 103d St., New York, N. Y. 10 cents.

"Health Services Tomorrow and Factors Determining Them," by Dr. Thomas Parran, Jr. *Public Health Reports*, Washington, D. C. April 13, 1934.

"Publications on Preventing Blindness." 1934 list of publications. National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y. *Free.*

"Answering the Call," a visiting nurse poster in color, with "When you are sick send for the Metropolitan Nurse." Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

From the Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y., comes a new edition of "The Baby." With a delightful baby face on the cover; 31 pages of text; and an index. *Free.*

"Diphtheria," with 2 pages of carefully selected, essential information, clearly presented. Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y. *Free.*

American Social Hygiene Assn., 50 W. 50th St., New York, N. Y., offers the following:

"Choosing a Home Partner," by N. W. Edson. 11 pages. 10 cents.

"Health for Girls." 14 pages. 10 cents.

"The Question of Petting," by M. J. Exner. 13 pages. 10 cents.

"Sex Education in the Home," by H. W. Brown. 14 pages. 10 cents.

"The Social Hygiene Program—Today and Tomorrow," by C.-E. A. Winslow. 24 pages. 10 cents.

HONORABLE MENTION

To Quebec Provincial Bureau of Health: for a limited "Table of Contents" in annual report.

To Milwaukee Health Department:

for an annual report which does not look like the output of an "official printer," and which has both "Contents" and "Index," and includes a section on "Health Education."

LANTERN SLIDES

A series of 13 charts on "Gonorrhea in the Male," available in miniature for 10 cents a set, are now issued as lantern slides, for sale or rental. American Social Hygiene Assn., 50 W. 50th St., New York, N. Y.

MAGAZINE ARTICLES

Here is background material; quotable matter; suggestions as to style and organization in writing.

"Marie Stopes, Crusader," by P. Allen. *Pictorial Review*. April, 1934. Sketch of the British Museum lecturer on paleontology who overthrew tradition so that the Ministry of Health now supervises birth control clinics.

"Arms and the Men." *Fortune*, 350 E. 22d St., Chicago, Ill. March, 1934. \$1. A devastating factual statement (illustrated) of munitions making as a chief source of war making. "Their axioms: (a) prolong war, (b) disturb peace."

"The Chicago Epidemic." *New Republic*, 420 W. 21st St., New York, N. Y. Feb. 28, 1934. 15 cents. "Chicago is proud of its fire, its fair and its epidemic."

"Cinchora—Quinine to You"; "The Great Radium Mystery"; "State Housing: American Style." *Fortune*, 350 E. 22d St., Chicago, Ill. Feb., 1934. \$1. Background material beyond public health aspects.

"Consolidated Cows." *Fortune*, 350 E. 22d St., Chicago, Ill. May, 1934. \$1. Background material on milk and milk products distribution. Milk bottle illustration may suggest a cover design for a "milk issue" or pamphlet.

"A Dental Clinic on Wheels," by Helen Hall. *Journal*, National Educa-

tion Assn., Washington, D. C. March, 1934. Traveling clinic of Little Rock public schools. Illustrated. 25 cents.

"Food for Athletes—And for All," by H. Ripperger. *New York Times Magazine*. April 1, 1934. (In many public libraries.)

"Freedom to be Young," by Karl N. Llewellyn. *Today*, 152 W. 42d St., New York, N. Y. March 10, 1934. 5 cents. An understanding, but impressive statement of opposition to the Child Labor Amendment—and the answers.

"Getting Well Again," by M. M. Miller. *Delinicator*. April, 1934. "Forethought and intelligent handling to avoid some of the pitfalls which result in prolonged difficulty for the (sick) child and for the family."

"Health against Odds," by Louis I. Dublin. *Woman's Home Companion*. April, 1934. "Since the beginning of the depression, when all sorts of values have been undermined if not destroyed, human life and health have stood up singularly unaffected." "A growing and very real hazard to the public health, however, now emerges from the economic situation."

"Heap Bad Medicine," by J. Mitchell. *New Republic*, New York, N. Y. Nov. 8, 1933. The fight against legal control.

"Paying Doctor's Bills," by Mary Ross, public health editor of *The Survey*. In *Today*, 152 W. 42d St., New York, N. Y. March 17, 1934. 5 cents. "Is medical care to continue as a private business arrangement or become a social right?" With full page illustration: "America meets the needs of every economic class in education and public safety. Full medical service as well must be brought within the reach of all to complete the circle of social protection."

"Public Health and Private Doctors," by D. L. Worcester; "Nurses Show the Way," by C.-E. A. Winslow;

"Sickness and the New Poor," by Edgar Sydenstricker; "Change Comes to the Doctor," by M. M. Davis; and numerous illustrations appear in *Survey Graphic*, 112 E. 19th St., New York, N. Y. April, 1934. 30 cents.

"The Safe Prenatal Diet," by Dr. Kate Daum. *Herald-Tribune Magazine*, New York, N. Y. Feb. 25, 1934.

"Tramp, Tramp, Tramp, the Girls Are Marching," by Margaret Fishback. *Delineator*. April, 1934. "Another point in favor of walking, as our country's fad for 1934. It's as convenient and thrifty as it is healthy and smart."

"Wasting Women's Lives," by H. H. Smith. *New Republic*, 421 W. 21st St., New York, N. Y. March 28, 1934. 15 cents. "The frightful toll of abortion."

"Who's Who in the Drug Lobby," by James Rorty. *Nation*, 20 Vesey St., New York, N. Y. Feb. 21, 1934. 15 cents. Patent medicine connections of opponents of drug bills.

"Young Doctor Heat," by Paul de Kruif. *Ladies' Home Journal*. April, 1934. "Old Doctor Sun is the best physician I know, but when he is not on the job I'm beginning to bank on his assistant, Young Doctor Heat."

NEW

At least new to us: *Chats*, Division of Public Health Nursing, State Dept. of Health, Albany, N. Y. Book shape; mimeographed; undated; 35 pages.

BULLETINS

Attention is called to the monthly *Bulletin* issued by the American Society for the Control of Cancer, 1250 6th Ave., New York, N. Y. The 12 pages monthly contain short practical articles written by authorities as well as news relating to cancer research and cancer therapy. "It presents an easy and practical way of keeping abreast of cancer control progress." \$1.00 a year; a sample free upon request.

It seems a pity that "Mark Time" and his pal, "Ben Hustler," should be limited to the fairly exclusive audience provided by *Public Health News*, New Jersey State Dept. of Health. Would it be worth a test to send this copy to the newspapers of the state in advance of publication in *Public Health News*?

"Meeting the Challenge of Rural Public Health," by Elma Rood, is a feature running in *Bulletin*, Kentucky Board of Health, Louisville:

Elizabeth Baker, a public health nurse, working in a pioneer field in far away Michigan, exchanges letters with her good friend and old schoolmate, Frances Brown, a rural teacher in the mountains of Kentucky. Each tells the other how a challenge in public health is being met and answered in their respective states.

"The Babies," with quotation from Mark Twain; "Prosperity Babies," "Ten Years of Combat with a Foe of Happy Childhood" (diphtheria), "Babies and Tuberculosis," "Safe Milk for the Babies," "The Baby's First Birthday," and a display page about diphtheria make up an effective "baby number" of a health department bulletin, with good use of local statistics and service information. This March, 1934, number of *Health*, Dept. of Health, New Haven, Conn., carries the following on the cover:

New Haven possesses all the facilities necessary to the safeguarding of the new-born infant and the preschool child. The reason our prosperity in Baby Welfare has not as yet reached its full fruition is because parents do not fully understand or utilize the varied opportunities.

Michigan Public Health, State Dept. of Health, Lansing, is one of the bulletins making good use of excellent copy first appearing in other bulletins, much of which is too useful to be limited to one city or state.

Santa Barbara, Calif., *Bulletin* used a large mimeographed "dollar" to show

how the medical-health dollar is spent. "Prevention or Cure—Which?"

"Hunger for Health Facts," by Iowa State Dept. of Health, Des Moines, tells what was wanted by 1,034 people at the State Fair. More than 15,000 pieces were requested. Washington and New York were among the outside states represented.

"Recovery and the Health Department," by D. J. Sullivan. *Health Bulletin*, New Jersey Tuberculosis League, Newark, N. J. March-April, 1934.

MOTION PICTURES

How to get that local motion picture is told in "Featuring a County Health Program in Motion Pictures," by L. C. Coleman, M.D., in *Bulletin*, State Board of Health, Louisville, Ky., Jan., 1934.

The Madison County Health Department has recently inaugurated an additional educational feature, in the form of a film designed to give a complete motion picture of the whole public health program in the county. This film, which is in two reels and is the production in which Dean Rumbold of the Eastern State Teachers College rendered invaluable assistance, has been altogether financed by the civic and women's clubs of Richmond and Berca, with no iota of pecuniary expense to the Health Unit, the county or the state. It constitutes a résumé in pictures, with appropriate titles and reading material, of all the different activities of the Health Department.

At this writing, the film has been shown to 8 different audiences, and there are numerous appointments for showings after the first of the year. The measure of enthusiasm which it has so far uniformly elicited would seem to justify the confidence that, in this film, we have an addition to our educational program which will materially assist in bringing about an even greater degree of coöperation than now exists between the citizens of Madison County and the Health Unit.

"Street Safety — for Advanced

Grades," and "Street Safety — for Primary Grades," are two new pictures by Eastman Teaching Films, 343 State St., Rochester, N. Y. 16 mm silent; outright sale only.

"1,000 and One" is the 1934 edition of "the blue book of non-theatrical films, their producers and distributors. Includes "Physiology, Health and Hygiene." *Educational Screen*, 64 E. Lake St., Chicago, Ill. 75 cents.

REPORTING

"Milwaukee's Health—1933" is the cover text of an especially pleasing annual report of 20 pages with cover. The ivory paper, frequent headings, selected illustrations, diagrams, and tables promise to serve this stated purpose:

This condensed report of the Milwaukee Health Department is published for the use of individuals and organizations interested only in general health information.

More detailed information may be obtained from complete reports filed in the Health Department, Municipal Reference Library and with the Mayor and Common Council.

An even more condensed report appears in the March, 1934, issue of *Bulletin*, Milwaukee Health Department.

"Reflections of 1933," and a baby picture with its reflection in the background, make up the cover of the annual report of the National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y. "Highlights of 1933"; no financial statement; 8 pages and cover.

"Union Health Center" is a small booklet reviewing 20 years' history and the services offered by this center which is maintained by two score labor unions. At 131 E. 17th St., New York, N. Y.

BOOKS AND REPORTS

Hygiene of the Mind—By *Baron Ernst Von Feuchtersleben*, Translated from the German by *F. C. Sumner, Ph.D.* Introduction by *Dr. Esther Loring Richards*. New York: Macmillan, 1933. 150 pp. Price, \$1.25.

This unique volume represents a series of essays written by a physician about 100 years ago. The author, as these essays clearly show, in addition to being a physician, was also a philosopher and poet. He was, in a very unusual way, an observer and went far in his interpretation of what he saw. He was not held down, in his efforts to understand the human being, by the limitations of the scientific store of knowledge as it then existed.

Of particular importance to those interested in mental health is the author's recognition of the very significant rôle played by the mind in what were ordinarily considered "physical diseases." He strongly emphasizes the rôle played by the will, emotions, and intellect as causative factors both in sickness and in health. The author's belief in the power of the will to cure almost any physical disease frequently broadens to the extreme. His emphasis on these forces is so strong that one wonders how a man trained so thoroughly in "physical medicine" was able to observe so well and reason so clearly on the psychological aspects of man's health. One cannot fail to admire the author's courage in presenting so forcefully these psychogenic aspects, particularly at a time when they were so little understood, and not recognized as they have been in recent years as very potent forces in both health and disease.

He also gives an important place to

religion and the efficacious part that it does or should play in the lives of human beings.

His suggestions for the maintenance of mental health are general in character, but the details as to how his suggestions should be carried out specifically can be filled in, to some extent, from our more recent knowledge, particularly that contributed by the psychoanalytic school. In this connection he discusses at some length the neurotic and particularly the hypochondriac.

This volume will prove interesting and stimulating to those interested in the historical background of mental hygiene. Surprisingly enough, the term "mental hygiene" occurs several times in these essays. The book is a translation of the third German edition of 1910. The author's style is very clear and the translator, without doubt, has contributed in no small way to the literary style that enhances its value to the reader.

FRANK J. O'BRIEN

Chronic Nephritis and Lead Poisoning—By *L. J. Jarvis Nye, M.B., Ch.M.* Sydney: Angus & Robertson, Ltd., 1933. 145 pp. Price, \$4.00.

The author claims to have brought to a logical conclusion the recent report of a Federal Inquiry into this subject in Queensland, but which investigation was not finished, apparently due to pressure of vested interests in the lead industry. As far back as 1892, Turner called attention to juvenile nephritis in Brisbane children. The subject was subsequently related to lead poisoning by Gibson in 1904.

The 5 chapters concern themselves with: (1) chronic nephritis in young people in Queensland, (2) lead poison-

ing in childhood in Queensland, (3) the relation between chronic nephritis and lead poisoning, (4) the source of the lead poisoning and its association with the chronic nephritis described, and (5) the problem for preventive medicine.

As a contribution to medical science the publisher claims this is perhaps the most important work to come out of Queensland since Bancroft discovered the adult filarial worm 57 years ago.

Every inhabitant of a wooden house in any part of the world should know something of lead paint and especially its liability to poison children. In the hot, tropical sun, but also in heated periods of the year anywhere, lead paint on exposed surfaces tends to powder very readily so that on walls, veranda railings and fences, it rubs off like chalk. Children contacting same, and especially children given to the habit of nail-biting and thumb-sucking, sum up the hazard.

The conclusions of Allbutt in the lead-arterial tension controversy in 1914 are amply supported in the present report. Lead is a vascular sclerosing agent.

The author blames apathy, "domestic deafness," and "social blindness" for doing nothing about it. "Were a new poison used in the manufacture of paint, the story would be entirely different . . . the extreme care to prevent poisoning from the new compound, ethyl lead, in motor spirit, is an excellent example."

Other factors commonly contributing to juvenile nephritis in Queensland are discussed in detail and dismissed one after the other, as hot sunlight on white-skinned people, the various acute infections, rickets, etc. The death rate from chronic nephritis in young people in Queensland (322 per 100,000 population) is unusual. From 1915 to 1930, there were 349 patients suffering from plumbism admitted to the wards of the Brisbane Children's Hospital. Female dependents, domestics, and male in-

dustrials were found to lead nephritis deaths in 9 occupational groupings—especially the first named; also, the poorer classes.

"These children have characteristic appearance with pallid, wizened features, dry and unnourished skin, and stunted physical development." Dwarfism is especially prominent. Cases commonly reach the mid-period of chronic lead poisoning even before investigation. Clinically, the most obvious sign is anemia, but all the other signs and symptoms of lead poisoning occur—the paralysis usually occurring in the legs rather than arms. Fortunately, cases have materially decreased since about 1926, attributed to education, earlier recognition, and the introduction of non-poisonous paints.

It seems paradoxical that commercial firms should take precautions in the care of their employees, whereas there should be such entire neglect of preventive measures against powdery lead paint. Probably it is because child life is outside of the practical gambit of commercial enterprise in which ill-health, sick benefits and compensation occur.

The reviewer would point out the all-too-frequent case reports of lead poisoned babies from paint and enamel on cribs and toys in America.

The present book is replete with tables, graphs and half-tones. It is written in a masterful but only semi-technical style, with conclusions at the end of each chapter and an extensive bibliography. There is no index but the table of contents is clear and the several pages of preface should not be overlooked.

E. R. HAYHURST

Nursing History—By Minnie Goodnow. Philadelphia: Saunders, 1933. 517 pp. Price, \$2.00.

When we received this book for review we looked at it and groaned "Another history of Nursing!" But we

had no sooner read a few pages than our spirits began to be lifted. For here was a history that did not dwell interminably on the details of nursing and medical practice back in ancient and medieval times, but discussed homely and human things to show the trend of the care of the sick up through the ages. For instance, the following subjects are discussed in rapidly moving paragraphs in the first chapter: "Nursing Among Animals," "Care of the Sick Among Savages," "Medicine and Theology," "Sickness and Sin."

For the first time we learned (and to remember) why the Crimean War was fought and who fought in it; what caused Florence Nightingale's long invalidism; when the medical profession first showed interest in nurses' training. We had never read of the Waltham Idea of training nurses before. The accounts of nursing in the Civil, Spanish-American, and World Wars were especially interesting.

The following statement made on page 253 left us in doubt as to what organization the author really meant, but we figured it must be the American Public Health Association: "The National Public Health Association openly proclaims its dependence upon the nurses of the country for the carrying out of its program."

The English is not as polished as it might be, but one gets a fine idea of the significant milestones in the history of nursing, and if we were a pupil nurse again studying history of nursing we would choose this text, for even after a long, strenuous day, we would find it too interesting to go to sleep over.

EVA F. MACDOUGALL

Growing into Manhood—By Roy E. Dickerson. New York: Association Press, 1933. 100 pp. Price, \$1.00.

A goodly proportion of books dealing with sex hygiene and written for young boys are mawkish and unconvincing,

largely, I suppose, because the authors themselves unconsciously share the public's rather shamefaced attitude toward sex. This book by Dickerson is not of that type. It impresses one as a straightforward attempt to talk sensibly and frankly with the boy as an older friend might to a younger one. The author does not falter and become obscure for fear of possibly offending. The presentation is almost uniformly clear-cut and convincing. The main theme is kept from over-emphasis by being made a part of general hygiene.

If one were to criticise at all it might be in the direction of suggesting that some of the anatomy and physiology may be rather difficult for the younger boys. Again, the section on alcohol and tobacco is not quite so well balanced as the rest of the book; although it must be confessed that a balance is not easily attained on a subject so full of controversial pitfalls, and especially in writing for boys whose heroes may be dads who might have to fall back on the old saw, "Do as I say, not as I do."

This book could be read with profit by many adults as well as by boys.

MERRILL CHAMPION

The Chinese Medical Journal, Nov.-Dec., 1933, Vol. XLVII, Nos. 11 and 12. Professor Fülleborn Memorial, Parasitology Number. Peiping, China: The Chinese Medical Association.

This number is a memorial to Professor Friedrich Fülleborn, Director of the Institute for Tropical Diseases at Hamburg, who died September 9, 1933. The editors explain that the necessity of publishing reports which are on the border line between parasitology and pure zoölogy in this journal is due to the fact that special journals on parasitology, microbiology, and pathology have not yet made their appearance in China.

The articles in this issue may be

divided into three groups; the first dealing with histopathology in relation to parasitic infections; the second devoted to infection with the *Microfilaria malayi*, which is here reported for the first time; and the third on Spirochaetoses. The articles show extensive research and careful study. The English is excellent throughout, and one cannot help feeling that the Chinese are far ahead of us in their use of languages. It is hard to imagine a series of articles written by Americans in Chinese which would be understandable to the people who speak and read that language.

The volume is abundantly and excellently illustrated. The Chinese Medical Association is to be congratulated in being represented by such a journal and such a group of investigators.

MAZÛCK P. RAVENEL

Diet and the Teeth. Part III. The Effect of Diet on Dental Structure and Disease in Man—By May Mellanby. *Special Report Series, No. 191. London: His Majesty's Stationery Office, 1934. Price, 5s net.*

In this third report of Mrs. Mellanby on vitamin D, a close study has been made of the histologic structure of dental tissues—normal and abnormal. Frequency and distribution of structural abnormalities from a large number of deciduous teeth, extracted and in situ, are noted. Charts have been compiled showing the frequency of caries on different surfaces, defects in relation to time of development, and variations in structure of different types of teeth in the same individual. Finally the association between imperfect structure and caries is shown.

A study of secondary dentine seems to show better structure and calcification when an adequate amount of vitamin D is available. Structure and calcification of secondary dentine is used as an index to the tooth's resistance to decay.

The geographical and racial distribu-

tion of caries has been a stumbling block to the vitamin enthusiasts, but Mrs. Mellanby has hit upon breast feeding as the caries immunizing factor common to these dentally favored people. As a matter of fact, this practice is stressed as the most important agent in the prevention of caries. The ground upon which this assumption is based seems a bit shaky. Granting that prolonged breast feeding is practised by some immune races in certain localities, the concomitance of events is hardly acceptable as scientific proof.

Anatomic defects, such as developmental pits and fissures, have always been recognized as the most important predisposing cause of a certain type of caries. If the claims made for correct diet are justified, this chink in the armor of the tooth could be eliminated. Unfortunately this theory does not solve the problem of cavities having their beginning on smooth surfaces.

The author of the preface cites as proving the value of the work the alleged fact that the White House Conference in 1930 accepted the nutritional effect on teeth as being the dominant factor in dental physiology and pathology, the implication being that Mrs. Mellanby's work was accepted without question. No reference was given, but we presume that the author referred to the *Growth and Development of the Child*, Part II. In that we find the statement that Mrs. Mellanby regards vitamin D as a specific factor in producing a perfect dentine. The summary of the chapter devoted to this subject says:

Vitamin B complex has only an indirect effect on the teeth by affecting the general nutrition of the whole organism. Vitamin C has a profound influence on the tooth pulp and formation of dentine. Vitamin D exerts a calcifying influence on the tooth pulp and the formation of enamel. The different angles of approach in studying the factors influencing teeth are perhaps the cause of apparent confusion in the evidence presented by various investigators. The profound influence

which the vitamins are known to have on the assimilation and utilization of available material is not yet completely worked out. The basis of the peculiarities of various species of experimental animals is only beginning to be appreciated as comparisons are made. Until these considerations are fully understood, the nutritional factors involved in the formation of sound teeth cannot be completely evaluated. It can be said without qualification, however, that nutrition is the most vital of all the influences deserving consideration.

Existing beliefs as to the causes of dental caries, branded the "mental contortion" in the preface, signed by the Medical Research Council, are disposed of in a high-handed manner, reminding the reader that clinical dentistry is apparently not represented in this investigation.

C. F. ELZEA

Kampfgaserkrankungen—(*The literature of pathology and treatment of chemical warfare gas diseases*)—By Dr. Otto Muntsch. (2nd ed.) Leipzig: George Thieme, 1934. 110 pp. Price, 9.6 Marks.

It is presumed that during the next period of major warfare, large groups of the civilian population may be subjected to the action of war gases. This prospect has prompted the author to seek the coöperation of Red Cross units throughout the world in the collection and appraisal of all possible information bearing on the prevention and treatment of injuries resulting from exposure to these toxic chemicals. The author states in substance, "with this point in mind the purpose of this book is to offer such knowledge as has been gathered from the different parts of the world as to ways and means for protecting the civilian population against the ravages of war gases."

In the several chapters are discussed such topics as the development of chemical warfare; the statistics derived from the late war; the general toxicology and classification of chemical fighting materials; the chemistry of outstanding

war gases; the special pathology and treatment of such war gases as phosgene, chlorpicrine, dichlor - diethyl - sulphide, leurolite, arsine, the oxides of nitrogen, carbon monoxide, etc. One of the most attractive features of this book is the number of illustrations in color, presenting the clinical appearance of various types of affections following war gas exposure. In addition various illustrations in black and white and in color, present the results of animal experimentation, the appearance of various organs at autopsy, etc.

At this very time, this book holds only limited value in the practice of medicine. Against that day when thousands of persons may be attacked through the medium of gas warfare, this book contains all of the substantial information available to the best known means of preventing the malaction of war gases, the diagnostic treatment of these conditions when produced, together with extensive discussion as to the prospective effects following in the wake of acute damage after exposure to gas warfare materials.

CAREY P. McCORD

Municipal Year Book—By Clarence E. Ridley and Orin F. Nolting. Chicago: International City Manager's Assn., 1934. 256 pp. Price, \$4.00.

This is the first edition of a year book for American Cities, and purports to be "an authoritative resumé of activities and statistical data of American Cities." Studies on Municipal Government in its different phases are being made on a wide scale due to a desire to discover what are the indispensable functions in city government and what are the most effective methods of administration and, more particularly, at the present time to find out how economies can be effected.

This book will be a decided help to all engaged in such studies, and valu-

able generally as a reference book. A directory may soon get out of date, but an up-to-date one, as the year book apparently is, is a convenience and a great time saver.

The concise articles by experts in different fields of municipal activity setting forth the outstanding changes which have taken place during the year are informative and especially valuable by busy workers. The brief review of the public health field is prepared by Dr. W. F. Walker, formerly Field

Director for the Committee of Administrative Practice of the American Public Health Association and now with the Commonwealth Fund. His wide acquaintance with health organization and public health activities enables him to give trustworthy opinions as to the main trends in public health.

There is appended to the *Year Book* a selected list of recent books and periodicals which is most useful as a reference list. JAMES WALLACE

BOOKS RECEIVED

MATERNAL MORTALITY AND MORBIDITY. A Study of Their Problems. By J. M. Munro Kerr. Baltimore: William Wood, 1933. 382 pp. Price, \$8.25.

YOU MUST RELAX. By Edmund Jacobson. New York: McGraw-Hill, 1934. 201 pp. Price, \$1.50.

SURVEY OF PUBLIC HEALTH NURSING. Administration and Practice. By the National Organization for Public Health Nursing. New York: Commonwealth, 1934. 262 pp. Price, \$2.00.

BRUCELLA INFECTIONS IN ANIMALS AND MAN. Methods of Laboratory Diagnosis. By I. Forest Huddleson. New York: Commonwealth, 1934. 103 pp. Price, \$2.25.

JAPANESE MEDICINE. By Y. Fujikawa. Translated by John Ruhrah. New York: Hoeber, 1934. 114 pp. Price, \$1.50.

YOUR GERMS AND MINE. The Story of Good and Bad Microbes. By Berl ben Meyr. New York: Doubleday, 1934. 389 pp. Price, \$2.75.

INTRODUCTION TO FOOD BACTERIOLOGY. By Andrew Moldavan. Lancaster: Science Press Printing Co., 1934. 172 pp.

THE STORY OF THE NATIONAL LEAGUE OF NURSING EDUCATION. By Helen W. Munson. Philadelphia: Saunders, 1934. 80 pp. Price, \$1.00.

THE MUNICIPAL YEAR BOOK 1934. An Authoritative Resumé of Activities and Statistical Data of American Cities. Editors—Clarence E. Ridley and Orin F. Nolting. Chicago: International City Managers' Association, 1934. 256 pp. Price, \$4.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Improving the Britisher's Health—Successes and accruing benefits of the British system of health insurance are recounted by a leader of the British Medical Association. The paper should be read by everyone interested in preventive medicine.

BRACKENBURY, H. B. Health Insurance in England. *New Eng. J. Med.* 210, 16:851 (Apr. 19), 1934.

Investigating Tuberculosis Contacts—The examination of family contacts, as a tuberculosis case finding method, should be confined to a more highly selected group of families, made after a detailed clinical study of the primary case. Otherwise, the method may prove a relatively poor case finding procedure.

DOWNES, J. Tuberculosis Case Finding in the Red Hook Area of New York City. *Milbank Quart.* 12, 2:134 (Apr.), 1934.

Sewage Treatment—Briefly reviewed to make a useful and informing summary of the latest methods of sewage disposal, this paper will give the sanitarian the knowledge he should have to be up-to-date.

EDDY, H. P. Recent Developments in Sewage Treatment. *Sewage Works J.* 6, 2:262 (Mar.), 1934.

Health Instruction Reduced to Its Rudiments—This experience in social hygiene education for Negroes in the City of New Orleans has much in it that can be adapted to other health promotion projects.

EDWARDS, M. S. Popular Health Education in Simplest Terms. *J. Social Hyg.* 20, 4:177 (Apr.), 1934.

Health Facts to Be Unlearned—In this long list of 23 health "beliefs," some of which are taught and some handed down with the family china, you

are almost sure to find a few which will affront your own pet delusions. This paper should be required reading for all sanitarians and would-be health teachers.

FORSYTHE, W. E. Things to Forget in Health Teaching. *Health and Physical Education.* 5, 3:18 (Mar.), 1934.

Stability of Brucella Strains—Passage of bovine strains of Brucella through several series of hogs caused no determinable change from the bovine to the porcine type.

GILMAN, H. L., *et al.* Passage of Bovine Brucella Through Swine. *J. Infect. Dis.* 54, 2:171 (Mar.-Apr.), 1934.

Hopeful Cancer Results—The percentage of cures in cancer of the breast has improved (in Massachusetts). Further reduction in mortality depends chiefly upon public education and the prompt and proper treatment of any abnormality of the breast.

GREENOUGH, R. B., *et al.* Cancer of the Breast; End Results (Two Papers). *New Eng. J. Med.* 210, 16:831 (Apr. 19), 1934.

Parrots or Parrot Fever—We know little more about the intrinsic nature of psittacosis today than we did 2 years ago; the fight is not yet won; and efforts to suppress the disease meet with constant opposition and are attended with many difficulties: so concludes this excellent survey of the whole subject.

HOCK, V. M. Psittacosis in the United States. *Pub. Health Rep.* 49, 14:451 (Apr. 6), 1934.

Better Swimming—Improvements in swimming pool management are set forth in sufficient detail to make the matter understandable by all sanitarians.

HYATT, C. A. Swimming Pool Sanitation. *Municipal Sanitation.* 5, 4:116 (Apr.), 1934.

Importance of Child Care—In England improvement in death rates of various age groups depends upon the date of birth. This finding is consistent with the hypothesis that the important factor in health during the whole life is the environment up to age 15, and that improved conditions in later years have little effect.

KERMACK, W. O., *et al.* Death Rates in Great Britain and Sweden. *Lancet*. 226, 5770:698 (Mar. 31), 1934.

The Future in Health Administration—The health service of tomorrow will conform inevitably to the governmental framework whatever that may be. If the previous political philosophy prevails, the traditional forms of health administration will continue, improved it is to be hoped. If the current economic changes move to the left, we shall see old age, unemployment, sickness and other schemes of social insurance. Whatever happens, we shall have little to say about it and must conform.

PARFAN, T. Health Services of Tomorrow. *Pub. Health Rep.* 49, 15:477 (Apr. 13), 1934.

Health of the Recent-Poor—“Comparisons among various groups of the surveyed population indicate that the ‘depression poor’ obtained more free care of all kinds, less total physician’s care, more total hospital care, and more care by a visiting nurse than was received by their neighbors who were in similar economic circumstances in 1929 but did not suffer material loss of income during the depression.

PERROTT, G. St. J., *et al.* Medical Care During the Depression. *Milbank Quart.* 12, 3:99 (Apr.), 1934.

How Many Public Health Nurses Are Needed?—Unfortunately you will not find an answer to the question in this paper. You will find, however, sug-

gestions about ways in which an answer may sometime be reached.

RANDALL, M. G. How Many Public Health Nurses Are Needed? *Milbank Quart.* 12, 2:160 (Apr.), 1934.

More Babies for the New-Poor—“Low social status, unemployment, and low income in 1932 went hand in hand with a high illness rate and increased malnutrition among children. It was in these same groups of families that a high birth rate prevailed . . . in families which could least afford, from any point of view, to assume this added responsibility.”

SYDENSTRICKER, E. and PERROTT, G. St. J. Sickness, Unemployment and Differential Fertility. *Milbank Quart.* 12, 2:126 (Apr.), 1934.

Tubercle Filtrates—It seems that the Berkefeld filtrate of tuberculosis cultures injected into animals produces certain atypical non-progressive infections. This convinced some research workers that they were dealing with an ultra-virus. These authors added to the same filtrate a few tubercle bacilli which produced exactly the same condition. Hence, they infer that it is necessary to assume, instead of an ultra-virus, that a leaky filter may have been at the bottom of the phenomenon.

WALKER, E. L. and SWEENEY, M. A. Microscopic Demonstrations of Acid-Fast Bacilli in Tuberculosis Filtrates. *J. Infect. Dis.* 54, 2:183 (Mar.-Apr.), 1934.

Predisposition to Cancer and Insanity—There may be some consolation in learning that if you are marked for insanity, there is less likelihood that you will develop cancer than if you are destined to remain outside the asylum, for cancer is definitely less frequent among the insane than the general population.

WARREN, S. and CANAVAN, M. M. Frequency of Cancer in the Insane. *New Eng. J. Med.* 210, 14:739 (Apr. 5), 1934.

ASSOCIATION NEWS

AN OPEN LETTER TO THE MEMBERSHIP FROM THE PRESIDENT OF THE ASSOCIATION

DEAR MEMBER:

Now is the time to determine your own Pasadena plans. The annual offering of the science and art, of theory and practice, of philosophy and news in preventive medicine, is ready for your consideration.

Exchange of useful facts, diversity and discussion of opinion, agreement on policies and methods are best accomplished face to face and eye to eye.

Read the provisional program (to be published in the July issue), and be persuaded of the compelling worth of its multitudinous topics, and be tempted by the privilege of asking and answering questions among your professional peers, to attend the Pasadena meeting of our Association.

All Members and Fellows west of the Mississippi will find this their nearest and dearest opportunity.

Distance will add enchantment for those who by accident of birth and occupation are called Easterners. To these in particular it should be said that travel to the coast never cost less than it will this summer, and no previous western meeting of the Association has been sponsored by so numerous, so well organized, or so hospitable a group of regional hosts as welcome us now to California.

General meetings will emphasize the social and international problems of American public health, current experiments in public service, and the increasingly intimate dependence of our security upon health in the other continents and nations.

As is often the case, laboratory

leaders offer us progress and promise in many lines. Meyer of the Hooper Laboratories reveals the enigma of mussel poisoning; H. W. Hill, the veteran sanitarian of Vancouver, brings wisdom on milk; the Smiths tell of fluorine, the new criminal in water supplies; and Sippy brings us to time with new light on dysentery; Pearl Kendrick brings the new pertussis technic from Grand Rapids; and Sara Branham advances information on meningitis.

Official commissions in Chicago, and A.M.A. meetings in Cleveland, and many individual inquiries by correspondence and personal visit have left many questions on amebic dysentery to be answered by national authorities at our symposium.

New Mexico, San Francisco, and Minneapolis will make additions to our knowledge of syphilis control.

School physicians will be drawn by their confidence in the ability of Shepard, Pratt, Gudakunst, and others, to give them fact and method to raise the quality of child health.

Young of Lansing on immunity to diphtheria; Kellogg of Berkeley on bacillary dysentery; Bonyne of Los Angeles on streptococcus epidemicus; Meyer of San Francisco on psittacosis, compete with other well known authors for attention in diagnostic and preventive procedures.

Tuesday morning will, in fact, be a General Session because of the universal professional and public interest in the program on Serving the Public for Health. This will doubtless be the

Health Officers' banner event, planned in a spirit of competition in well-doing, not as a controversy between partisans.

Australia, Tennessee, and New York City will lay their experience at the feet of the health officers in other section meetings.

Occupational hygiene interests will center about the basic industries of oil, smelting, and lumbering, with original reports from Legge and others.

With Alonzo Taylor, Guy Millberry and Carl Alsberg dealing with nutrition, there will be crowded halls and eager listeners.

Child health has drawn its speakers from the Atlantic Coast to Hawaii—city and county official and nonofficial agencies.

For the epidemiologist in addition to the perennial problems of typhoid, syphilis, diphtheria, and scarlet fever from east and west, we have psittacosis,

particularly featured by Californians.

The Section Secretaries and the Program Committee offer a balanced feast of reason to whet our intellectual appetites. Come and share it and contribute as critical listeners and by your constructive discussions.

Come from near and far, come for your pleasure and for the profit of all of us.

Show your confidence in recovery by investing in this annual pilgrimage for public health.

Cordially yours,

HAVEN EMERSON, M.D., *President*

P.S. You will receive additional dividends on your investment in the form of good companionship and valuable professional contacts if you travel to Pasadena on the A.P.H.A. Special Train. If you have not received an invitation to join it, by all means inform the Association office in New York.

MAKE RESERVATIONS EARLY

IT will be necessary this year to use two hotels in Pasadena and the Civic Auditorium for section and general meetings. Since all the events of the Annual Meeting cannot be held under one roof and there will be considerable passage between the hotels, delegates will probably indulge their tastes this year so far as their personal headquarters are concerned more generally than at previous meetings when, for the most part, convention activities were centered in one hotel.

The principal hotels are listed below with their rates. The Vista del Arroyo, the Huntington and the Maryland are the best.

Registration and information, commercial exhibits, and certain section meetings will be held in the Maryland. The Huntington, too, will have some sessions and some luncheons and dinners. The Maryland is in the center

of the city; the Huntington is a 10 minute ride from the downtown area, set in its own beautiful 28 acre park. The Local Committee will provide transportation between the Auditorium and the Huntington, and between the Maryland and the Huntington, so that those wishing to surround themselves with unusual loveliness and comfort, such as the Huntington provides, may do so without sacrificing time and convenience.

The Maryland, too, is spacious and comfortable, with many attractive bungalows, surrounded with flowers and lawns, available for delegates in addition to rooms in the main building.

The best accommodations in both the headquarters hotels are double rooms. The number of single rooms is limited, and delegates are urged to make immediate reservations for them. Doubling up is recommended, in so far as possible.

PASADENA HOTEL RATES

The Maryland Hotel and Bungalows

(Capacity, 375 Rooms)

Single room, with bath, \$3.50-\$4.00
 Single room, without bath, \$2.50
 Double room, with bath, \$5.00
 Double room, without bath, \$4.00
 Bungalow rooms at same prices as Main Building rooms, \$4.00 additional for living room.

The bungalows vary in size, and consist of a living room and anywhere from 2 to 5 bedrooms, either with private bath or connecting bath, and these would make ideal arrangements for groups that would be congenial together.

The Huntington Hotel and Bungalows

(Capacity, 292 Rooms)

Single room, with bath, \$4.50
 Double room, with bath, \$6.00-\$7.50
 2 Single rooms, with bath, \$7.00
 Double and single rooms, with bath, \$9.00
 2 Double rooms, with bath, \$10.00

Hotel Green

(Capacity, 167 Rooms)

Single room, with bath, \$2.50
 Double room, with bath, \$3.00-\$3.50
 2 Single rooms, with bath, \$5.00-\$6.00

Hotel Vista del Arroyo and Bungalows

(Capacity, 400 Rooms)

Single room, with bath, \$4.50
 Double room, with bath, \$6.00-\$7.50

Hotel Constance

(Capacity, 164 Rooms)

Single room, with bath, \$2.00
 Double room, with bath, \$3.00

City..... State.....

RAILROAD RATES TO PASADENA

The American Public Health Association applied this year, as usual, for reduced railroad rates on the convention basis of fare and one-third for the round trip to the Annual Meeting. The passenger associations have advised that summer excursion rates are more favorable and are in effect in most sections of the country. We are instructed to advise members to confer with their home ticket agents, who will be able to

give them detailed information regarding fares, routes, and Pullman rates. This year you require no identification certificate in making your travel arrangements to Pasadena, since summer excursion fares are open to the general public. The following lists 45-day, round trip, summer tourist fares to Pasadena and Los Angeles from principal points. Pullman charges are not included.

RAILROAD RATES FROM VARIOUS CENTERS TO PASADENA, CALIF.

45-Day, Round Trip Summer Tourist Fare to Los Angeles

From:		From	
Atlanta	\$100.65	Nashville	93.15
Baltimore	120.75	New Orleans	85.15 (1)
Boston	133.98	New York	126.90
Buffalo	109.55	Omaha	72.00 (1)
Chicago	86.00 (1)	Philadelphia	122.85
Cincinnati	97.00	Pittsburgh	107.10
Cleveland	101.35	Portland (Ore.)	45.95 (2)
Dallas	70.45 (1)	Salt Lake City	30.85 (2)
Denver	57.50 (1)	San Francisco	19.50 (2)
Detroit	98.30	Seattle	53.30 (2)
Duluth	86.00 (1)	St. Louis	81.50 (1)
Fort Worth	70.45 (1)	Washington, D. C.	120.75

Milwaukee	86.00 (1)		
Minneapolis	86.00 (1)		

INTRODUCING THE CHAIRMAN OF THE LOCAL COMMITTEE ON ARRANGEMENTS FOR THE PASADENA ANNUAL MEETING

DR. J. D. DUNSHEE

WHILE the members of the Association know Dr. Dunshee's name very well for his work as Health Officer of Pasadena, and that he has recently been appointed Director of Public Health for the State of California, they will be interested to know the roads he has traveled to bring him to his pres-

ent post. If the following biographical material appears sketchy, his friends will know it is because he has insisted upon the removal of every adjective and every phrase that would seem to carry with it a suggestion of commendation. Dr. Dunshee came to California in 1920. During that winter he conducted

a weekly conference at the *Los Angeles Evening Express* for children of pre-school age.

Following this, he was appointed Director of Child Welfare of the Los Angeles City Health Department, a position which he held for 5 years. He resigned from the Health Department and served as Executive Secretary for the Southern California Society for Mental Hygiene. He has been on the Board of Directors of this Society for the past 10 years, serving as President for 1 year. It is under this Board that the Child Guidance Clinic of Los Angeles and Pasadena is operated.

Dr. Dunshee organized the Normandy Avenue Nursery School operating under the Board of Education of the City of Los Angeles, and has been active in all movements having to do with child welfare.

While in Los Angeles, Dr. Dunshee was a member of the Southwestern Pediatrics Society, and for 2 years was on the Pediatrics Staff of the Los Angeles General Hospital.

Early in 1929 Dr. Dunshee was appointed Health Officer of Pasadena. For the past 5 years, since its inauguration, Pasadena has been one of the honor cities in the Inter-Chamber Health Conservation Contest, in cities of 50,000 to 100,000 population. For the year just completed, Pasadena was first among the honor

cities in its population class. It has been through Dr. Dunshee's efforts that health work in Pasadena has been organized in such a way as to receive this recognition. Dr. Dunshee inaugurated the Health Section of the Council of Social Agencies in Pasadena which has met monthly and has worked closely with the Health Department on health programs. The outstanding contribution which he made to health work in Pasadena was securing the coöperation and support of all health agencies in the city. He was also sent by the City of Pasadena as a delegate to the White House Conference on Child Health and Protection in Washington, D. C.

On March 17, 1934, Dr. Dunshee was appointed Director of the California State Department of Health, an appointment welcomed by health workers of the entire state. His new work has in no way detracted from his interest in the Pasadena Annual Meeting. As *Chairman* of the Local Committee, his energies and enthusiasm are unbounded. Dr. Dunshee is a Fellow of the Association.

ADDITION TO PASADENA LOCAL COMMITTEE

Dr. J. D. Dunshee, *Chairman* of the Pasadena Local Committee, announces that Dudley M. Dorman, of Los Angeles, has accepted the chairmanship of the Finance Committee.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

James A. Dumas, M.D., 470 Broadway, Lynn, Mass., Public Health Commissioner
Herbert C. Hageman, M.D., 14 Fremont St., Gloversville, N. Y. (Assoc.)
William J. Maby, M.D., 515 Park Ave., Mechanicville, N. Y. (Assoc.)
Clyde R. Newell, M.S., 50 Hudson St.,

Hackensack, N. J., State District Health Officer
Irvin B. Trapp, M.D., Box 386, New Albany, Miss., Director, Union County Health Dept.
Frank D. Ursone, M.D., Norfolk, Conn., Health Officer
William D. Weis, M.D., Crown Point, Ind., County Health Commissioner

Lee J. Whittles, M.D., 351 Main St., Glastonbury, Conn., Health Officer

Laboratory Section

Gordon E. Davis, Sc.D., U. S. Public Health Service, Hamilton, Mont., Bacteriologist
Dr. Karl J. Demeter, Weißenstephan, Freising, Bavaria, Head, Bacteriology Dept., South German Research Institute of Dairy Science (Assoc.)

John H. Dingle, Sc.D., Upjohn Co., Kalamazoo, Mich., Bacteriologist

Mary A. Lynch, 4812 Fifth Ave., Los Angeles, Calif., Laboratory Assistant, City Dept. of Water & Power

Irwin M. Walker, M.D., Niagara Falls Memorial Hospital, Niagara Falls, N. Y., Director of Hospital Laboratory

Vital Statistics Section

Herbert H. Marks, A.B., 1 Madison Ave., New York, N. Y., Statistician, Met. Life Ins. Co.

Francis D. Rhoads, M.A., 1504 Alaska Bldg., Seattle, Wash., State Registrar

Mortimer Spiegelman, M.E., 163 Eastern Parkway, Brooklyn, N. Y., Research Clerk, Met. Life Ins. Co.

Victoria M. Trasko, 326 S. Main St., Wilkes-Barre, Pa., Statistician, Board of Health

Public Health Engineering Section

Howard R. Fullerton, C.E., State Dept. of Public Health, Nashville, Tenn., Assistant State Director of Malaria Control

William J. Lenz, M.D., Ph.D., 1346 Starks Bldg., Louisville, Ky., Consulting Chemist

Edgar B. Peebles, 1814 Cephas Ave., Nashville, Tenn., Dairy Inspector (previously Sanitary Officer)

Felix Seligman, Water & Light Dept., Duluth, Minn., Manager

Industrial Hygiene Section

Irving Gray, M.D., 41 Eastern Parkway, Brooklyn, N. Y., Member, Public Health Committee, Kings County Medical Society

Carroll Lockard, M.D., 10 South St., Baltimore, Md., Medical Director, Maryland Life Insurance Company of Baltimore

Food and Nutrition Section

Gordon W. Molyneux, 42 Barker Ave., White Plains, N. Y., Milk Inspector, Westchester County Dept. of Health

J. Y. Phelan, 705-49 Ave., N., Nashville, Tenn., Sanitary Officer

Child Hygiene Section

Youslin S. Blanchard, A.B., 11526 Linwood Ave., Detroit, Mich., Director, Health and Physical Education, City Public Schools

Charles E. Rink, M.D., 27 South 9th St., Indiana, Pa., Medical Inspector, Public Schools

Elma Rood, M.A., State Board of Health, Louisville, Ky., Assistant Director, Public Health Education

Public Health Education Section

John R. Heller, Jr., M.D., State Dept. of Health, Nashville, Tenn., Consultant, Venereal Disease Control

Alexander V. Morgenstern, 415 Central Park West, New York, N. Y. (Assoc.)

Ivan L. Ressler, E. I. duPont de Nemours & Co., Niagara Falls, N. Y., Consultant on Fumigation Problems, R. & H. Chemicals Dept.

Theodore R. Rhea, C.P.H., Dept. of Public Instruction, Honolulu, T. H., Director of Health Education

George Schwartz, M.D., 2487 Davidson Ave., Bronx, N. Y., Chairman, Public Health Committee, Lions Club

Kate H. Trawick, 2501 Ashwood, Nashville, Tenn., Associate in School Health Education, State Dept. of Public Health

Public Health Nursing Section

Grace Beatty, R.N., Greeneville, Tenn., County Nurse

Iter D. Boyette, R.N., P.H.N., 3197 Kinross Ave., Nashville, Tenn., Field Nurse, Davidson County Health Dept.

Dollie Burkitt, 4503 Charollette Ave., Nashville, Tenn., Field Nurse

Helen J. Greer, R.N., Dept. of Public Health, Franklin, Tenn., Supervising Nurse

Barbara L. Klassy, R.N., Franklin, Tenn., Tuberculosis Clinic and Field Service Nurse

Shirley C. Titus, A.M., R.N., School of Nursing, Vanderbilt University, Nashville, Tenn., Dean and Professor of Nursing Education

Estelle West, R.N., 1012 Mayner Ave., Nashville, Tenn., Public Health Nurse

Epidemiology Section

George T. Blydenburgh, M.D., C.P.H., Ohio Wesleyan University, Delaware, O., Director, Student Health

Bruce H. Douglas, M.D., Herman Kiefer Hospital, Detroit, Mich., Tuberculosis Controller, Dept. of Health

Unaffiliated

Ralph P. Bridgman, 60 E. 42 St., New York, N. Y., Director, National Council of Parent Education

Will G. Sheffer, D.D.S., Medico Dental Bldg., San Jose, Calif. (Assoc.)

William F. Stein, M.D., P. O. Box 703, Fresno, Calif., County Health Officer

CLOSING DATE FOR ACCEPTING APPLICATIONS FOR FELLOWSHIP

ACTIVE members who wish to make application for Fellowship in the American Public Health Association, are hereby notified that their applications must be submitted to the Committee on Fellowship and Membership not later than July 1, 1934, if final action is to be taken by the Governing Council at the Pasadena Annual Meeting in September.

For the benefit of the newer members

of the Association, the two prerequisites for applying for Fellowship are repeated here. These are (1) the applicant must have been an active member of the A.P.H.A. for at least 2 years, and (2) he or she must be at least 30 years of age. The professional qualifications which are essential are given in the By-laws, which appear on page 13 in the *Year Book* issued as a supplement to the February *Journal*.

NEWS FROM THE FIELD

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

ADA E. SCHWEITZER, M.D., F.A.P.H.A., Indianapolis, Ind., resigned as President of the Association of Women in Public Health, effective May 1, 1934.

The former Vice-President, Ellen Stadtmuller, M.D., member A.P.H.A., San Francisco, Calif., is now President and will plan the Association program for the convention to be held at Pasadena during the session of the A.P.H.A.

The Secretary is Pauline Brooks, F.A.P.H.A., Williamson, School Health Bureau, Welfare Division, Metropolitan Life Insurance Co., New York, N. Y.

The Treasurer is Alice C. Bagley, member A.P.H.A., Assistant Superintendent of Nursing, Metropolitan Life Insurance Co., San Francisco, Calif.

Mary R. Lakeman, M.D., F. A.P.H.A., Chairman of the Health Knowmeter Co. of the Association of Women in Public Health, announces that this most valuable card index of health information is ready for distribution. Questions concerning con-

tents and cost should be addressed to her at 100 Nashua St., Boston, Mass.

CONFERENCE OF STATE AND PROVINCIAL HEALTH AUTHORITIES AND U.S.P.H.S.

THE U. S. Public Health Service joins the Conference of State and Provincial Health Authorities of North America in extending to you a cordial invitation to attend and take part in the Annual Conference of the two organizations, to be held in the Public Health Service Building, Washington, D. C., June 5-8, 1934.

CALIFORNIA HEALTH DEPARTMENTS
MERGE

THE San Leandro Health Department and the Alameda County Health Department, of California, have combined and will function under the direction of Dr. Ira O. Church, Health Officer, of Alameda County, member A.P.H.A. Dr. Luther Michael retired as Health Officer of San Leandro, having held the position many years.

NEW CANCER CLINIC

THE establishment of the Atlanta Cancer Clinic, for pay patients,

has been authorized, with headquarters in the Medical Building of the Georgia Baptist Hospital, Atlanta, Ga. A diagnostic fee commensurate with the patient's circumstances will be charged, the funds to be used for the maintenance of the clinic. The Clinic will have available 370 mg. of radium.

Dr. James L. Campbell has been named Director of the Clinic.

SUMMER CAMP FOR MILWAUKEE GIRLS

PHI Delta Pi, National Professional Physical Education Fraternity for Women, will establish a Camp for Underprivileged Children at Camp Brosius, Elkhart Lake, Wis., in July. The campers are to be 10 and 11 year old girls who live in the congested districts of Milwaukee. They are to be recommended by social agencies to the advisory committee of the Summer Outing Fund.

Martha A. Gable, Director of Physical Education in Junior High Schools in Philadelphia, is to be Camp Director. Miss Hazel C. Orr, Director of Physical Education in Woodward High School of Cincinnati, is Grand President. Phi Delta Pi is a member of the Women's Professional Panhellenic Association.

NEW PSYCHIATRIC CLINIC

THROUGH a recent gift of \$80,000 from the Rockefeller Foundation, the establishment and maintenance of a psychiatric unit at the Massachusetts General Hospital, Boston, Mass., is now in prospect.

Of this sum, \$42,000 will go to Harvard Medical School for psychiatric work and the remainder will be available for the establishment of the clinic, the construction of which will begin in September. Dr. Stanley Cobb, Bullard Professor of Neuropathology at Harvard, will direct the project. Close cooperation will be established with McLean Hospital, of Belmont, Mass.,

which has recently been reorganized, for the treatment of the more difficult cases.

HEBREW UNIVERSITY PLANS CANCER RESEARCH

A TRUST fund of approximately \$200,000 (£39,000) has been created by anonymous donors to be used over a period of 10 years for the establishment and maintenance of a department at the Hebrew University in Jerusalem for research into the causes and cure of cancer.

Part of the available funds will be used for the erection and adequate equipment of special laboratories.

OREGON STATE BOARD OF HEALTH ELECTS OFFICERS of the Oregon State Board of Health recently elected in Portland are:

Dr. Albert Mount, President; Dr. Joseph P. Brennan, Vice-President; and Frederick D. Stricker, F.A.P.H.A., Secretary.

FOR GRADUATE NURSES

FOR nurses interested in studying the behavior of and having practical experience in working with young children, a course is being given at the Child Development Institute of Teachers College, Columbia University, New York, from June 11 to July 6. Intensive experience with well children will be provided under supervision in the nursery school and play group and regular classes and individual conferences will be held to analyze and study the behavior of the children as well as the technics of guidance used in working with them.

DRS. RIDDLE AND MCCOLLUM RECEIVE MEDALS

THE American Institute awarded gold medals to Dr. Oscar Riddle, member A.P.H.A., and Dr. E. V. McCollum, F.A.P.H.A., at a meeting

on May 3 at the American Museum of Natural History, New York, in recognition of their respective achievements in the fields of research on the glands of internal secretion and of nutrition.

DIPHTHERIA IMMUNIZATION IN DALLAS

DUE to the fact that Dallas has been shown to have the highest diphtheria morbidity and mortality of any city in the United States, the Department of School Health Work recently undertook a survey of immunization in the public schools. The survey has been conducted in 46 elementary schools, in which 27,094 children were enrolled.

NEW ARKANSAS STATE BOARD OFFICERS

AT a recent meeting of the Arkansas State Board of Health, Dr. Joseph G. Gladden was named President; Dr. Thomas Wilson, Vice-President; and Dr. William B. Grayson, member A.P.H.A., Secretary.

UNIVERSITY OF MINNESOTA RECEIVES GIFT

THE University of Minnesota recently received a gift of \$500,000 for the advancement of medical research from Dr. William J. Mayo, and Charles H. Mayo, member A.P.H.A., of Rochester, Minn.

PERSONALS

HAVEN EMERSON, M.D., Professor of Public Health Practice at Columbia University College of Physicians and Surgeons, President A.P.H.A., and **DR. FRANK L. BABBOTT, JR.**, President of Long Island Medical College of Brooklyn, N. Y., were appointed members of the Board of Health of New York City by Mayor LaGuardia. Dr. Emerson was Health Commissioner of New

York from 1915 to 1918. Dr. Emerson will make a survey of tuberculosis in the city at the request of the Department of Hospitals.

DR. EDWARD H. SKINNER, member A.P.H.A., has been appointed Chairman of the Public Health and Welfare Committee of the Chamber of Commerce of Kansas City, to succeed Dr. George E. Bellows, who has resigned after 12 years' service.

DR. SAMUEL J. ELLISON, member A.P.H.A., who had been Health Commissioner of Adams County 14 years, is succeeded by Dr. Hazel L. Sproull, of West Union, Ohio.

DR. FRANK R. DEW, member A.P.H.A., of Barnesville, has retired from the office of Health Officer of Belmont County, which he occupied for 11 years.

DR. CHARLES E. THOMPSON, of Mingo, Ohio, has been appointed Health Officer of Champaign County after a lapse of several months in which the county was without a health head because of lack of funds.

DR. FRANCIS M. TEEPLE, of Fremont, Ohio, has been named Health Officer of Sandusky County.

DR. ARNOLD O. ABRAHAM, of McConnelsville, Ohio, succeeds Dr. James B. Naylor as Health Officer of Morgan County.

DR. WILLIAM L. FAUL, of Russellville, succeeds Dr. John G. Anderson, of Fayetteville, as Health Officer of Brown County, Ohio.

DR. FAY E. GAITHER, of Lenora, has been appointed Health Officer of Norton County, Tex.

DR. EBER REEVES has been named Health Officer of Decatur County, Kans.

DR. JOHN I. MITCHELL, of Salem, Ind., has been made Health Officer for Washington County, succeeding the late Samuel A. Roberts.

DR. DARREL L. EVANS has been named Health Officer of Riley County,

Kans., succeeding Dr. John R. Mathews, of Manhattan, who resigned to engage in private practice in Glenwood Springs, Colo., after holding the position since 1923.

DR. BASIL B. BRIM has been named Health Commissioner of Toledo, Ohio, now a part-time office.

JOHN L. JONES, M.D., of Louisville, Ky., was appointed recently Assistant Utah Health Commissioner and State Epidemiologist. He assumed his new duties in his native state on April 20 for the first time. The post of epidemiologist has been vacant since 1929 due to lack of funds. The added expense will be shared by the state and the International Health Division of the Rockefeller Foundation.

DEATH

HARRY L. ABRAMSON, M.D., member A.P.H.A., and Director of the Bureau of Laboratories of the New Brunswick Department of Health at Saint John, N. B., since 1918, died in New York on April 17. Dr. Abramson, whose home was in St. Joseph, Mo., was associated with Dr. William H. Park in the Research Laboratories of the City of New York before he joined the New Brunswick Department of Health.

CONFERENCES

June 1-2, Annual Conference, New England Health Education Association, Massachusetts Institute of Technology, Cambridge, Mass.

June 5-6, 7th Annual Meeting, Arizona Public Health Association, Prescott, Ariz.

June 4-8, Annual Convention of the American Water Works Association, Hotel Commodore, New York, N. Y.

June 5-8, Annual Conference of U. S. Public Health Service and Con-

ference of State and Provincial Health Authorities of North America, Public Health Service Building, Washington, D. C.

June 11-13, Twenty-third Annual Meeting of the Canadian Public Health Association, Montreal, Que., Canada.

June 13-16, 13th Annual Convention of the American Physiotherapy Association, Cleveland, Ohio.

June 14-15, Annual Convention, Central Atlantic States Association of Dairy, Food and Drug Officials, Baltimore.

June 18-23, Summer Meeting of the Council of the American Association for the Advancement of Science and Associated Societies, Berkeley, Calif.

June 25-29, 7th Annual Meeting of the American Home Economics Association, New York, N. Y.

June 26-28, Annual Conference of Health Officers and Public Health Nurses, Saratoga Springs, N. Y.

June 26-28, American Association of School Physicians, Saratoga Springs, N. Y.

June 27-29, 8th Annual Conference of the Pennsylvania Sewage Works Association, State College, Pa.

July 9-14, Health Congress, to be held under auspices of the Royal Sanitary Institute, Bristol, England

Aug. 6-10, Annual Meeting of the American Dental Association, St. Paul, Minn.

Sept. 3-6, 63rd Annual Meeting, American Public Health Association, Pasadena, Calif.; headquarters, Huntington Hotel and Maryland Hotel.

Sept. 4-6, 9th Conference of the International Union Against Tuberculosis, Warsaw, Poland.

Oct. 15-18, 17th Annual Meeting of the American Dietetic Association, Washington, D. C.

Nov. 13-16, Southern Medical Association, San Antonio, Tex.

Industrial Intoxication Following Skin Sorption *

CAREY P. McCORD, M.D., F.A.P.H.A.,
*Medical Director, The Industrial Health Conservancy Laboratories,
Cincinnati, Ohio*

THE Nineteenth Session of the Industrial Hygiene Section opened as part of the Sixty-second Annual Meeting of the American Public Health Association.

By custom, if not by constitutional requirement, the Chairman is obligated to present some introductory considerations pertinent to the affairs of the section. In the past, the greater number of chairmen have elected to estimate existing conditions, and to indicate desirable trends for the future. In the present instance, we appear to be at a junction point—between a past period filled with ills well known to everyone, and the beginning of new departures into which we have not progressed sufficiently to permit of estimation of their values to industrial hygiene.

On this account, the present Chairman sounds no keynote, and instead desires to make general rather than technical comment on a phase of industrial hygiene that may be much

neglected, *i.e.*, toxicity following the entry of various substances through the skin.

The mechanisms by which many substances accomplish passage through the skin are little known. On an empiric basis, it has become established that numerous medicaments and intoxicants penetrate the skin; and, conversely, that others are barred. With the possible exception of fat-dissolving agents, the entering substances are often so dissimilar as to stultify any belief in the commonness of properties permitting absorption.

The singular status of skin permeability is reflected in a number of contrasting examples. Boric acid solutions, applied to the healthy skin, appear in one minute in the urine; but citric acid of equal strength, similarly applied, is said to be wholly unabsorbed. Moreover, borates, with a physiologic action closely resembling boric acid, do not enter the skin when placed in contact.¹ Hydrocyanic acid gas readily passes through the skin, and may produce poisoning after this form of entry, but carbon monoxide gas does not so enter, or at best only in traces. Tetraethyl lead penetrates the unbroken skin,

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

but solutions of inorganic lead compounds are not known to pass this portal in quantities susceptible to measurement. Substances closely related chemically are likely to present the widest differences in ability to enter the body through the intact skin.

The entire present situation is such that only by trial may the fate of any agent with an unknown status as to skin absorbability be determined. Thirty-five years ago Schafer² wrote:

To decide the case for or against the possibility of absorption by the human skin, would appear a simple problem, yet a literature reaching back over a century indicates that the production of unimpeachable testimony on either side has proved a matter of no little difficulty. . . .

That statement is equally true today!

Not until 1932 was it established, on a quantitative basis, that iodine—one of the commonest medicaments—applied to the skin is absorbable. Nyiri and Jannitti,³ after referring to the evenly matched controversy for the past 65 years as to the skin absorption of iodine, established that iodine and iodides penetrate the unbroken skin; that 12 per cent only of the amount painted onto the skin is at the disposal of the skin; that 4 per cent is the maximum taken up by the skin in the first few hours after application; and finally that at the end of 3 days (after application) up to 5 per cent of the total iodine is still within the skin; 7 to 9 per cent having entered the body through the blood or lymph. This precise sort of information is widely lacking, especially for industrial intoxicants, which agents are most likely to lead to damage, because of the extent of exposure.

Industrial hygiene long has emphasized the respiratory tract as the chief portal of entry of industrial intoxicants. By contrast, the skin, as a portal of entry, has been relegated to an insignificant position. Masks, respirators,

helmets, etc., have been provided helpfully to protect the respiratory tract against invasion, without a thought for the skin. Development of intoxications among workers well guarded against inhalation of toxic vapors, gases, etc., is increasing the consideration extended to skin absorption as a factor in the causation of occupational diseases, chemical accidents, etc. Practical hazards are being proved to exist.

FACTORS INFLUENCING SKIN SORPTION

1. Sustained, profuse sweating eventuating in an alkaline perspiration, may deprive the skin of its oily protection, and facilitate skin absorption.
2. Circumstances leading to an hyperemia of the skin promote skin absorption.
3. Breaks in the integument, such as from a dermatitis or trauma, favor entry into the body. Such entry may not, however, constitute true skin sorption.
4. Fat-dissolving agents, such as naphtha, may themselves enter the body or create opportunity for other substances to find entry through the skin.
5. Friction applied to the skin, such as the inunction of mercury ointments is conducive to skin absorption.
6. Failure to free the body of contact with materials that may enter the skin is related to the practical dangers of skin absorption of industrial intoxicants.
7. Naturally, oily skin offers additional difficulties to the entry of some substances.
8. The younger the skin, the greater the probability of skin sorption by that particular skin, up to the years of senility, and in the absence of skin injury.
9. Cataphoresis may thrust into the skin substances not otherwise absorbable.

THE MECHANISMS OF SKIN SORPTION

It is most unlikely that any one physical principle governs the passage of chemicals through the skin. Boric acid undoubtedly enters through osmosis; adsorption may play a significant rôle in connection with hydrocyanic acid. Undoubtedly, certain substances find entry by way of the sebaceous glands, and only so. Rubbing may lead to mechanical deposition within the hair follicles and glandular spaces.

Surface tension, plasmolysis, diffusion streams, molecular size, and capillarity, all contribute some influence upon the physics of skin penetration. Withal, it is most difficult to determine the demarcation point between normal skin and damaged skin, in relation to these several physical activities. Manifestly, a chemical dermatitis is preceded by some such physical injury to the cells as may be accomplished by plasmolysis.

Reduced to its simplest basis, it appears probable that the characteristic shared by all substances that penetrate the normal skin (in the absence of friction, cataphoresis, etc.) is the capacity for "cell wetting."

This activity of cell wetting is far more complex than is implied in the simple example of water being barred from the skin by the oily film there present, and the function of soap in breaking down this interposed incompatible layer. The behavior of mercury when in contact with metallic lead, furnishes a more acceptable concept of "surface wetting."

If metallic mercury be placed in contact with a piece of lead, the mercury enters and diffuses in all directions. In time the lead becomes crumbly, or at least brittle. It might be assumed that compounds are formed between the lead and the mercury—but such is not the case. Appropriate electrical tests reveal that the lead is unchanged. What has happened is that the mercury, having the peculiar property of "wetting the crystals" of lead, has seeped in between all the faces of the crystals, and in time has made the lead mass crumbly, by depriving the lead of its inter-crystal cohesion. This relationship between lead and mercury is not equally true for mercury and iron, or mercury and cadmium. In the former, the mercury does not permeate the iron (that is, does not wet the crystals); in the latter permeation does occur, but with combinations between the cadmium and the mercury.

If this concept of "crystal wetting" be transferred to "cell wetting," it becomes possible to understand how some substances pass between successive layers of epidermal cells until brought in contact with those deeper skin layers richly supplied with blood and lymph vessels. In the corium sorption is readily accomplished.

SKIN ABSORBABLE SUBSTANCES

In furnishing a list of substances (not all of which have industrial uses) believed to pass the skin barrier, no intent exists to imply that the list is complete, that practical hazards regularly are involved, or that proof of skin sorption for every item on the list is incontrovertibly established.

Ammoniated mercury	Iodides
Anilin oil	Iodine
Belladonna	Kerosene
Benzene	Lanolin
Benzine	Lard
Bismuth	Mercury
Boric acid	Mononitrochlorbenzene
Camphor	Naphtha
Carbon bisulphide	Nicotine
Carbon tetrachloride	Nitranilin
Chlorine	Nitrobenzol
Chloroform	Nitronaphthalene
Creosote	Oleates
Cresols	Olive oil
Croton oil	Osmium
Cyanides	Oxides of mercury
Cyanogen compounds	Paranitranilin
Dimethylanilin	Phosphorus
Dimethyl sulphate	Phenacetin
Dyes (some)	Phenol
Ether	Picric acid

Hydrocyanic acid	Turpentine
Hydrogen sulphide	Vaseline
Ichthyol	Zylene

PRACTICAL HAZARDS

The usual workman, exposed to an industrial intoxicant that may enter the skin, is likely to be inhaling the vapor,

gas, or fume, at the same time. Occasionally workers who are adequately masked for protection against dangerous substances, still may become intoxicated. Notably this is true in the case of workers about hydrocyanic fumigation of buildings or ships.⁴ Despite protection for the respiratory tract, skin absorption is likely to lead to practical damage from the following substances:

Nitrobenzol, and some of its closely related compounds

Anilin oil, and some of its closely related derivatives and compounds

Hydrocyanic acid, possibly including all cyanogen compounds

Phenol and cresol, including some related coal tar derivatives and compounds, such as picric acid

Tetraethyl lead

SUMMARY

It is the purpose of this presentation to maintain that no adequate body of information is now available as to the mechanisms of skin absorption, or the extent of practical dangers attending industrial skin exposure. If this stand be the correct one, it follows that this field provides opportunity for constructive inquiry.

Psittacosis Outbreak in Pittsburgh

IN a total of 37 cases of illness among the employees a definite diagnosis of psittacosis was made in 10, and of suspected psittacosis in 27. Of the 10 definitely diagnosed as psittacosis, 4 died, autopsies on 3 of whom revealed the findings seen in psittacosis. Of the 27 suspected cases, 8 were diagnosed pneumonia, of whom 7 died, and 19 as suspected psittacosis only, of which number 2 died. Among the total of 37 cases there occurred 13 deaths, a mortality rate of 35.1 per cent. This rather high mortality rate suggests either an extremely virulent outbreak or that cases of the disease had been missed. From the procedures carried out by the health department it is believed that but few cases were missed, as each employee absent from work for 48 hours was seen by a medical inspector.

With a history of contact with sick birds of the psittacine family, with 10 other employees having illnesses definitely diagnosed as psittacosis, with a death rate of 33.3 per cent, and with

a death rate of 87.5 per cent of those diagnosed as pneumonia, there is little doubt that the 27 cases of suspected psittacosis were actually cases of psittacosis.

These 37 cases of illness developed among approximately 500 employees of a department store and occurred not only among those employed on the floor on which the birds were kept but among those from other floors. Employees from other floors of the store visited the birds, and these employees came in more or less direct contact with them.

SUMMARY

During the past 4 years, 2 rather extensive outbreaks of psittacosis have occurred among employees of department stores in which pet shops were maintained. The first resulted from infected birds which had been imported into the country, and the second from birds raised at an aviary in California. —Extract from L. F. Badger, *Pub. Health Rep.*, May 11, 1934, p. 584.

Pollution Indices of Natural Bathing Places*

W. L. MALLMANN, PH.D., AND ADOLPH SYPIEN
Michigan Engineering Experiment Station, Michigan State College,
East Lansing, Mich.

ALTHOUGH indices of pollution have been established from time to time for bathing pools, few attempts have been made to set standards for natural bathing places. California¹ has proposed a standard of 10 *Escherichia coli* per c.c. and the New York City Department of Health¹ allows 30 *Esch. coli* per c.c. Winslow and Moxon² in a study of New Haven bathing beaches believe that an average of 1 colon bacillus per c.c. with a maximum of not over 10 would be a more reasonable standard as based upon conditions that obtained in their studies. Scott³ in a study of Connecticut's shore waters on Long Island Sound classified bathing waters into 5 classes according to the colon indices obtained:

Average of <i>Esch. coli</i> per 100 c.c.	
Class A+	0 to 10
Class A—	11 to 50
" B	51 to 500
" C	501 to 1,000
" D	over 1,000

In correlating the bacteriological findings with a sanitary survey, the classification in representing bathing beach qualities is as follows:

	Condition
Class A+	good
" A—	good
" B	fair to doubtful

Class C
" D

Condition
doubtful to poor
very poor

All of these studies were planned primarily to measure sewage pollution of bathing beaches and not the conditions that would occur in clean waters when large numbers of bathers were present. Scott³ states that only a slight increase in bacterial numbers occurred on an ocean beach during periods of heavy bathing loads. He believes that the number of bacteria introduced by the bathers would not seriously affect his classification. In a survey of the coast line of lower Michigan, the Michigan Stream Control Commission⁴ found results similar to those obtained by Scott in salt water beaches. Colon indices on Lake Michigan beaches that were a considerable distance from sources of sewage pollution frequently were from 0 to 100 per c.c. of water. Such areas undoubtedly represent ideal bathing places.

The conditions that occur, however, on the Great Lakes and ocean beaches are quite different from those occurring on small inland lakes. These lakes, because they frequently do not receive any raw sewage, have been assumed to be safe for bathing. This is largely true, but to date no recognition has been given to the pollution introduced by the bathers. As these lakes are frequently located near large cities, they

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

FIGURE I—Map of Lake Lansing showing location of bathing beach and sampling points

have become very popular. In lower Michigan these lakes are generally small and bathing areas, open to the public, are frequently limited in size. Beaches from 200 to 400 ft. in length are very common. Near the large cities such beaches become very congested on the warm days of August and July.

As no attempt has been made to study the bacteriology of such beaches, the work here presented was done.

A lake near East Lansing was selected due to its convenience, its freedom from sewage pollution, and the presence of a limited size bathing beach that has a heavy patronage. The beach is, in most respects, typical of most inland lakes in the lower part of Michigan. In Figure I is presented a map to show points of sampling, location of the bathing beach, and size of lake, which is approximately $1\frac{1}{4}$ miles long by 1 mile wide at the widest point. The only bathing beach is at the northern end. The control point for collecting samples as checks on the bathing beach, is at an amusement park

$\frac{3}{4}$ mile south of the bathing beach on the west side, and was selected largely because of its convenience. No sewage enters the lake. It is very active biologically. Samples taken at any point show large numbers of plankton. Rotifers and water fleas are very common. In Figure II is presented a map of the beach, showing its size and

FIGURE II—Profile map of the bathing beach

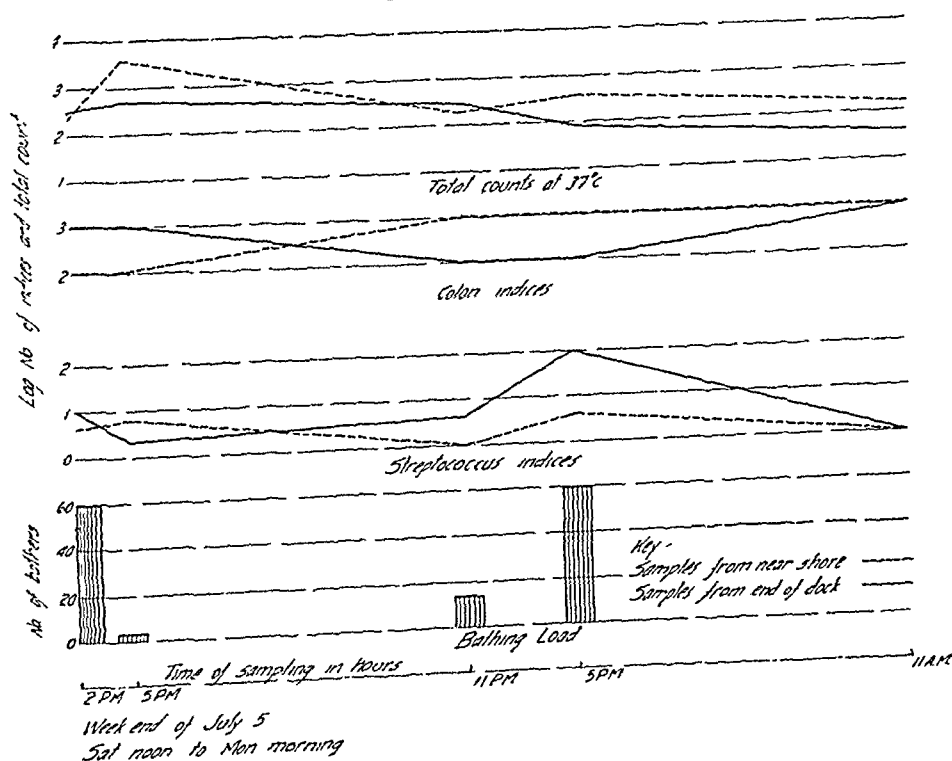

depth. It will be noted that it is sharply circumscribed by an area of soft muck, so the bathers always remain in the sandy area, about 350 ft. long, 200 ft. wide, and approximately 5 ft. deep at the deepest point. The bottom slopes very gradually. The heaviest bathing load is found at B. A bathing dock with diving platform is located here. Most of the bathers enter the water from this dock and generally stay in the close vicinity of it.

It was desired to obtain data on the bathing beach under all conditions such as light and heavy bathing loads, various temperatures, and rest periods. Samples were usually collected at frequent intervals during week-ends; in periods of use and of rest. In most cases samples were obtained early in the morning before bathers arrived, following a day of heavy loads. It was found most satisfactory and most convenient

to collect two samples, one at the end of the bathing dock and the other from the dock near the shore in approximately 18 in. of water. Occasionally sand samples were taken at the latter point, particularly in the morning, to determine the influence of sedimentation on the disappearance of the bacteria over night.

The samples were collected in the usual large mouth glass stoppered water sample bottles. Immediately after collection, the following bacteriological examinations were made: Appropriate dilution plates were made using standard plain nutrient agar, and incubated at 25 and 37° C. Bacteriological counts were made after 24 hours' incubation at 37° C. and 48 hours' at room temperature, respectively. Appropriate dilutions of the water were made into standard lactose nutrient broth in Durham fermentation tubes. Generally, the series was 1 to 100,000,

GRAPH I—Comparative data on pollution indices of samples taken from the end of the bathing dock and near the shore

GRAPH II—Comparative data on pollution indices from samples collected at the bathing beach during the week-end of June 23

1 to 10,000, 1 to 1,000, 1 to 100, 1 to 10, 1 c.c., and 10 c.c. direct. Observations were made at the end of 24 and 48 hours' incubation. Tubes showing gas from the least amounts of water were smeared on eosin-methylene blue agar for confirmation of the colon bacillus. All questionable cases were further checked by refermentation in lactose nutrient broth fermentation tubes. After 72 hours' incubation, 48 hours' at 37° C., followed by 24 hours' at room temperature, all tubes were examined for streptococcus microscopically by the method recommended by Mallmann and Gelpi.⁵ Indices for both the colon bacillus and streptococcus are based on 100 c.c. volumes of water and were determined by the procedure recommended by *Standard Methods of Water Analysis*.⁶

At first, samples were taken at three points on the bathing beach to assure obtaining average results, but this was soon found impractical due to inability to handle the large number collected. After careful examination of the data so obtained and a study of the beach itself, it was decided to sample at only one point—that of greatest pollution as

evidenced by the density of bathers. This was a bathing dock located at one side of the beach.

The results for this week-end are representative of all the data, and show the relationship between samples from the end of the dock and those from near shore. It will be observed that the colon indices and the total count are somewhat parallel. In general, the colon indices and total count were slightly higher near shore. On the contrary, the streptococcus indices were generally higher at the end of the dock. The latter was to be expected as the total immersion of the body is more frequent in the deeper water. Because the samples from the end of the dock gave results on total count and colon indices comparable to the samples from near shore and higher streptococcus indices, only samples from the end of the dock will be considered.

As the week-end bathing loads were always much higher than those obtained during the week, these periods were selected for more intensive study. Each week-end the sampling was started on either Friday or Saturday afternoon and continued until Monday

morning, depending upon weather conditions. Samples were taken late at night after bathing had ceased and early in the morning before bathing started. In this manner the fall and rise in the pollution could be observed. In Graph II are presented the results of a typical week-end test. It will be observed that, in general, all three indices of pollution parallel roughly the bathing load, although the streptococcus index parallels it more closely; also that the number of colon bacilli and the total counts are considerably higher than the number of streptococci. This is just the opposite of the condition in a chlorinated swimming pool where the chlorine destroys the more susceptible colon bacilli and leaves only the streptococci. The total count in a chlorinated pool may also be lower due likely to the fact that the streptococci do not appear on the agar plate.

It might be argued that all three in-

dices of pollution were equally good, though, if the control samples, taken a safe distance from the beach, are compared with the samples taken at the time of heavy bathing loads, another picture is presented, as in Graph III. It will be observed that the total counts of the bathing beach and the control area are roughly parallel, as also are the colon indices. Both of these indices show a diurnal rise, which may be due to the rise in temperature. In the case of the streptococcus index, no streptococci were observed in any dilution of the samples tested in the control samples. On days when no bathing occurred, streptococci were absent. Generally in the sample collected in the morning, even following days of heavy loads, the streptococcus incidence was low or negative.

The results presented in Graph III concerning the parallelism between the colon indices on the bathing beach and

GRAPH III—A comparison of pollution indices from samples collected on the bathing beach and a control point free from pollution during the week-end of July 22

GRAPH IV—Comparative data of colon indices from the bathing beach and control area during period of study

on the control area are more strikingly presented in Graph IV where the colon indices for the period of study are presented. The averages for these areas were practically the same.

Graph V shows the results of tests on total count for the bathing beach and the control area. The total counts for the bathing beach are, on the average, considerably higher than the control area; however, there is considerable overlapping of the counts. In Graph VI are presented the data on streptococcus indices for both the bathing beach and the control area. Here the indices for the control area are zero throughout, while a very marked fluctuation occurs in the bathing beach samples.

Graphs IV, V, VI also show the importance of repeated sampling before passing judgment upon natural bathing areas using any bacteriological index. It will be observed that catch samples taken on most any day or night might show either acceptable or unacceptable conditions when based on any of the three pollution indices presented.

The use of sand samples did not give any added information. In general, they showed total counts and colon indices slightly higher than the water samples taken at the same spot just before. The sand samples did show that sedimentation did not account for the appearance of the streptococci overnight, as the morning sand samples were negative to tests for these organisms.

The samples taken in the center of the lake always showed lower counts than those collected near shore at the same time. The results of these tests did not give any additional information; hence the data are not presented.

On ocean and large lake beaches it is conceivable, and very probable, that currents due to wind and tides cause such changes in water that dilution removes the bacteria introduced by the bathers. Further, the large size of such beaches and the corresponding volume of water in the bathing area give such great dilution that no appreciable increase in the numbers of bacteria would be expected. However, in the light of the data here presented, the writers feel that samples collected during heavy bathing loads might show results similar to those found on the beach discussed.

Contrary to accepted opinion, the writers believe that momentarily a natural bathing beach is not different

GRAPH V—Comparative data on total counts from the bathing beach and control area during the period of study

from a circumscribed indoor or outdoor bathing pool. This is particularly true of the type of beach used in this study. This beach, due to the muck areas that bound it, is very closely demarcated. Very few bathers venture beyond the 200 ft. limit due to the weeds and muck that begin there. These natural barriers delimit the beach as effectively as a wall. As Mallmann and Cary⁷ found that in a sterile chlorinated pool the bacterial counts rose rapidly after the introduction of heavy loads, it is quite conceivable that changes of water on the beach are so slow that during periods of heavy loads this factor can be ignored as a means of purification. That this is true is borne out by the data which show that the streptococcus indices rise with the bathing load and disappear gradually after discontinuance of bathing. It would seem logical to treat such beaches in a manner similar to unchlorinated indoor pools. That the

bathing loads should be limited accordingly seems obvious. If the pollution introduced into an artificial pool by the bathers is to be considered dangerous, it seems highly illogical that the same pollution on a bathing beach should be ignored. Why insist on drinking water standards for an artificial pool and have extremely liberal or no standards for the natural beach?

It is true that the number of *Escherichia coli* in the swimming pool and in the waters of natural beaches are not comparable; however, the data in this paper, and in earlier ones by the senior author, have demonstrated that the streptococci do measure the pollution introduced by the bather. Although no standards for streptococcus incidence are offered, it is possible to devise a standard for this organism that can be applied equally well to either artificial or natural bathing places. To arrive at a standard it will be necessary to collect a large volume of data by workers in various parts of the country under various conditions. It is hoped by the writers that the committee on swimming pools and bathing places will undertake such a project.

That the *Esch. coli* test, which serves as the best index of the sanitary

GRAPH VI—Comparative data on the streptococcus indices from the bathing beach and the control area during the period of study

purity of a water supply, is not necessarily infallible as an indicator of unsanitary conditions is again emphasized by the writers. The senior author has demonstrated that *Esch. coli* is not the best indicator of swimming pool pollution, and again in this paper it has been demonstrated that this organism does not measure the pollution introduced by the bather in sewage-free bathing beaches. It must be remembered that in a water containing large amounts of organic matter *Esch. coli* grows abundantly even in the absence of sewage or bathing pollution and thus ceases to be an indicator of pollution. The same holds true of the 37° C. total count.

SUMMARY

The most representative samples of the bathing beach water were obtained in 5 ft. of water as compared to samples taken near the shore. This was particularly true of the streptococcus indices.

The colon indices and the 37° C. total count did not always respond to changes in bathing loads. These indices obtained on the bathing beach were not markedly different from indices obtained at points free from pollution at the same time.

The streptococcus index fluctuated

with the bathing load. Streptococci were not found at points free from bathing pollution.

The streptococci disappeared over night. The colon and total counts indices sometimes showed an increase over night, although they were generally lower.

Catch samples in no instance should be used as a measurement of the sanitary condition of a bathing beach.

The need of controlled bathing loads on limited inland lake beaches appears essential. Conditions on the limited bathing beach presented were similar to those obtained in indoor and outdoor swimming pools.

The Effectiveness of Vaccines Used for the Prevention of Typhoid Fever in the United States Army and Navy

PAUL R. HAWLEY, M.D., DR.P.H.

Major, Medical Corps, U. S. Army; Instructor in Biometry, Army Medical School, Washington, D. C.

AND

JAMES STEVENS SIMMONS, M.D.

Major, Medical Corps, U. S. Army; Director, Department of Preventive Medicine, Army Medical School, Washington, D. C.

THE practical results obtained with specific typhoid prophylaxis indicate that, while this procedure does not confer an absolute immunity, it has been of great value in reducing the incidence of typhoid fever among troops, even when living under insanitary conditions. However, because of the lack of a suitable laboratory test of vaccine potency, there has been some uncertainty as to the exact degree of protection afforded by vaccination, and considerable speculation as to the relative merits of different typhoid vaccines.

With the development of newer concepts of the various antigenic changes which may accompany visible dissociative alterations in bacterial cultures, attempts have been made to utilize such information in establishing exact criteria for the selection of cultures most suitable for use in typhoid vaccines. Theories recently evolved from studies of bacterial variation have led certain individuals to question the value of vaccines prepared with sub-strains of the well known Rawlins culture of typhoid bacillus, on the assumption that during their long period of cultivation on artificial media these cultures may have lost

certain characteristics necessary to an effective immunizing agent. These theoretical objections to the Rawlins strain have been based largely on cultural and immunological reactions observed in the laboratory, and there has been considerable disagreement as to their validity.

Since a sub-strain of the Rawlins culture has been employed in all typhoid vaccines prepared at the Army Medical School and used by both the Army and Navy, those responsible for the manufacture of these vaccines have naturally been interested in determining whether this culture is still suitable for vaccine production. In searching for the answer to this important problem it must be borne in mind that while theoretical considerations based on antigen-antibody reactions may be suggestive, the only known measure of the protective action of a typhoid vaccine is the incidence of typhoid fever among large groups of vaccinated individuals.

It is the purpose of this paper briefly to review the history of typhoid vaccination; to recount the experience with the U. S. Army sub-strain of the Rawlins culture; to discuss various fac-

tors, including dissociation, which might have influenced the protective action of the vaccines; to correlate these factors with the incidence of typhoid fever; and to determine, if possible, to what degree the vaccines now in use conform to the requirements of a satisfactory prophylactic agent.

EARLY HISTORY OF TYPHOID VACCINATION

The possibility of artificially immunizing human beings by the inoculation of typhoid bacilli was naturally suggested at an early date by the successful use of vaccines for the prevention of certain other diseases, and by the observation that one attack of typhoid fever usually protects against subsequent infection.

During the latter part of the 19th century many investigators attempted to test this possibility by vaccination experiments with laboratory animals, including guinea pigs, rabbits, and mice. Chantemesse and Vidal¹ (1888) and subsequent workers showed that such small animals, which could be killed in a short time by the inoculation of large numbers of living typhoid bacilli, might also be protected against the fatal toxic reactions by the preliminary injection of killed typhoid cultures. Because of the natural resistance of these animals to spontaneous typhoid infection, and their failure to develop a disease resembling typhoid fever, such experimental results were not considered as directly applicable to the problem of typhoid prophylaxis in man. However, discovery of the fact that the vaccination of animals produced specific antibodies, including agglutinins, bactericidal bodies, and bacteriolysins, similar to those found in the blood of typhoid convalescents, led to the hope that the presence of these antibodies might furnish a reliable index of immunity. Such observations, and the work of Haffkine on cholera im-

munization, stimulated interest in the possibility of protecting man against typhoid fever by the use of vaccines.

During 1896 Pfeiffer and Kolle,² in Germany, and Wright,³ in England, inoculated suspensions of killed typhoid bacilli into human beings, observing that this procedure was safe and that it was followed by an increase in antibodies in the blood of such individuals. In 1897, Wright⁴ suggested the use of typhoid vaccines in armies and hospitals; and started his pioneer work which constitutes the real beginning of specific typhoid prophylaxis. During the next few years he and Semple⁵ prepared vaccines from killed broth cultures of typhoid bacilli, with which they inoculated several thousand British soldiers in India and a number of persons in England. During the Boer War he and Leishman furnished 400,000 doses of vaccine for voluntary use among the English troops; and it is estimated that about 100,000 men were inoculated. While the vaccination records for the Boer War were incomplete, Wright⁶ concluded that among those inoculated the incidence was diminished about 50 per cent and the mortality even more. However, for the entire Army with a total strength of 380,605 the typhoid incidence rate was 151.56 per 1,000 and the mortality was 21.08 per 1,000. Such appalling rates created a very unfavorable impression, and there were many reports claiming that the vaccine not only failed to protect but had actually increased the number of cases and deaths. Consequently, toward the end of the War, typhoid inoculation was stopped in the British Army and a commission was appointed to re-investigate the subject.

As a result of their statistical studies this commission,⁷ in 1904, made an interim report in which it was recommended that inoculation be resumed as a voluntary measure in the British

Army; and that experimental work be undertaken with a view to increasing the effectiveness of antityphoid vaccination. The investigations, which were continued for several years by Leishman and his associates, produced valuable information, and led Leishman⁸ in 1910 to conclude that, while various factors might have played a part, the disappointing results of vaccination during the Boer War were almost entirely due to irregularities in the preparation and standardization of the vaccines. Consequently the older methods were modified in a number of ways including: (a) the selection of a more suitable strain of typhoid bacillus, (b) the use of cultures grown in nutrient broth for 48 hours instead of 10 to 16 days, (c) reduction of the killing point from 60–65° C. to a maximum of 53° C., (d) cooling of the heated suspension before the addition of 0.4 per cent lysol, (e) standardization of the vaccine by Harrison's modification of Wright's counting method, (f) reduction of the dose to $\frac{1}{2}$ and 1 c.c. amounts, of a 1 billion per c.c. suspension, and (g) adoption of an expiration date of 3 months.

ORIGINAL SELECTION OF THE RAWLINS STRAIN OF *E. TYPHI*

In view of the present question as to the relative immunizing value of different strains of typhoid bacilli, it is of interest to note that this problem was given serious consideration in 1904 by the British commission.⁷ In their effort to produce the most satisfactory vaccine possible, for military use—that is, one combining maximum protective action with sufficiently low toxicity—they investigated various strains of *E. typhi*, including old cultures, and others which had recently been isolated from cases of typhoid fever. It was observed that “all strains did not behave alike when grown under identical conditions,” and the conclusion was

reached that “it was not clear upon what this variability depended as no constant factor such as age, virulence, length of time since isolation, etc., was found.” The commission selected as most suitable for use, in the British Army vaccine, the now well known Rawlins strain of typhoid bacillus, which was isolated in 1900 from the spleen of a fatal case of typhoid fever and had already been cultivated on artificial media for a period of 4 years.

In discussing the reasons for adopting the Rawlins strain, Leishman⁸ called attention to the current controversy as to the relative merits of cultures of high and low virulence; and stated that an attempt was made to settle this point by animal experiments using two vaccines: “one prepared from our usual non-virulent strain, the other from a strain recently isolated from a fatal case of enteric fever and which was found to possess a high degree of virulence for guinea pigs.” The two vaccines were inoculated into rabbits in amounts comparable, on the basis of weight, to the doses used in man; and quantitative estimations were made of the various protective substances which appeared in the blood during the following weeks. While the first experiments showed a slight margin in favor of the vaccine prepared from the recently isolated, more virulent strain, this was not confirmed, as in later experiment both vaccines gave identical results. Consequently Leishman made the following statement:

We concluded that a virulent strain might perhaps be expected to give rise to a slightly higher degree of immunity but that the difference in this respect was not marked. We have also convinced ourselves by many experiments that the protective substances elaborated in response to inoculations of a non-virulent vaccine are highly active *in vitro* against a freshly isolated and virulent strain of *Bacillus typhosus*. We have made no change then in this respect, but adhere to the use of a strain of typhoid which has been long sub-cultured in the laboratory, and now

possesses but a very slight degree of virulence for guinea pigs. We are influenced in this decision, however, by another factor—namely, the fact that vaccines prepared from a virulent strain of *B. typhosus* give rise in man to more severe reactions both local and general.

It is extremely probable that not all strains of non-virulent typhoid bacilli are equally suitable for use in vaccines; we have reason to believe that that which we employ is exceptionally so. Wassermann considers that the virulence of the organism is not of so much importance as its affinity for the specific amboceptors and in this our non-virulent strains excel.

In view of the recent interest in dissociation it is of importance to note that certain physical growth characteristics were also considered in selecting the Rawlins strain. To quote Leishman⁹:

It was originally intended to employ for this purpose a strain "G," isolated from the spleen at Netley 5 years ago, which had been largely employed by Dr. Wright and myself in the preparation of vaccine, and is still employed by Dr. Wright for this purpose. In our preliminary work, however, it was found to possess the disadvantage of being a strain which could only be emulsified from an agar culture with great difficulty and at the sacrifice of more time than we were likely to be able to afford. Further experiment resulted in the selection of another strain "R," of similar origin and of about the same age, which had also been extensively employed at Netley in the preparation of vaccine. This strain was one which furnished a very even and satisfactory emulsion from an agar culture and was thus more suitable for some parts of the delicate experimental work which lay before us. Both these strains being of low virulence, and of proved suitability for inoculation, preference was accordingly given to that which promised to give more regular results in our test experiments, and the strain "R" was, therefore employed, both in the preparation of the vaccine and in the daily quantitative tests of the protective substances developed in the blood of the inoculated.

Thus it appears that when adopted for use in the British Army vaccine in 1904, the Rawlins strain, which was then 4 years old, was selected because of its relatively low toxicity for guinea pigs and man, its satisfactory stimulation of certain antibodies and because

it had at least one characteristic of what has since been designated as a smooth type of *E. typhi*; that is, it produced a uniform diffuse growth in broth, and suspensions from agar cultures were not agglutinated by physiological salt solution.

This strain was used by the British Army from 1904 until 1933; and a sub-strain obtained in 1908 has been used since that date in all typhoid vaccines manufactured for the United States Army and Navy. Still other sub-strains have been furnished to public health and commercial laboratories throughout the world; and it seems safe to say that the descendants of the so-called Rawlins culture of typhoid bacillus have been used more extensively than any other for vaccine production. Thus by virtue of extensive use in prophylactic vaccines, if for no other reason, this strain has acquired an importance which demands for it serious consideration.

THE U. S. ARMY SUB-STRAIN OF THE RAWLINS CULTURE

Typhoid vaccination was introduced into the U. S. Army in 1908 by General F. F. Russell who, after a thorough study of the procedures used in the English and German Armies, adopted a modification of the two methods and selected for use in the American vaccine a sub-strain of the British Rawlins culture. In a discussion of antityphoid vaccination in 1913, Russell¹⁰ commented on this strain as follows:

The English vaccine is, therefore, a killed broth culture made from a single strain of the bacillus, which was originally selected because it emulsified well from agar slants. Preliminary trials of this organism showed that it agglutinated well in immune serum, and produced in good quantities all measurable kinds of antibodies in animals and man. This strain is still in use in England and in our military service, and although we have searched from time to time for a strain with greater antigenic properties, none has yet been found.

As this same Rawlins sub-strain has been used continuously in our Army, it has been responsible for whatever protection we have derived from typhoid vaccination. However, from time to time theoretical objections have been raised concerning its relative effectiveness.

THEORETICAL OBJECTIONS TO THE RAWLINS STRAIN

In 1917 Weiss¹¹ questioned the advisability of using the Rawlins strain in vaccines, on the assumption that it belonged to a relatively small subgroup which differed from the majority of typhoid cultures. He reported that, of 31 typhoid strains which he investigated, 6 failed to produce acid in xylose broth, and that 4 of these appeared to be atypical antigenically in that they did not absorb agglutinins for the xylose-fermenting strains. Observing that a Rawlins strain was one of those that failed to ferment xylose, Weiss made the following statement:

We wish also to emphasize that on a basis of these results we believe that in typhoid prophylaxis the single "Rawlings" vaccine may not give complete protection. Recent cases of typhoid fever among soldiers who have received the prophylactic treatment have come to our attention and lend weight to our belief. We would recommend that a polyvalent vaccine, or one made from an organism which is more representative of the whole group should be used.

However, Teague and McWilliams,¹² by plating and selecting different colonies of a single culture of *B. typhosus*, showed that differences, with regard to the absorption of agglutinins, could be obtained at times with these subcultures, similar to those obtained by Weiss when using his xylose-fermenting and non-fermenting strains. Therefore, it was decided that the evidence offered by Weiss did not warrant the addition of other strains to the vaccine prepared at the Army Medical School. During 1918, strains of typhoid bacilli that

apparently failed to ferment xylose were encountered in cultures obtained from certain American soldiers in France; and the question of xylose fermentation was investigated under the direction of General F. F. Russell, by Teague and Morishima.¹³ These workers studied 116 strains of typhoid bacilli including the U. S. Army, Rawlins culture, and discovered that all of them fermented xylose, although about 8 per cent were slow fermenters—acting through the production of "daughter colonies." Similar observations were made concerning the fermentation of arabinose, and other sugars; and it was concluded that there was no evidence to justify Weiss's suggested division of typhoid bacilli into separate groups.

More recently there has been some question as to the value of typhoid vaccines in general, because of observations which indicate that the inoculation of vaccines into man fails to produce the so-called somatic or "O" type antibodies in such concentrations as are observed after recovery from typhoid fever. While flagellar and somatic antigens were differentiated in 1903 by Smith and Reagh,¹⁴ their significance was not recognized until later when Weil and Felix¹⁵ and their followers investigated the "H" or flagellar and the "O," or somatic antigens, of *Proteus* X19, and later extended these observations to organisms of the typhoid-paratyphoid group. In 1924 Burnet¹⁶ showed that both the "flocular or H" and the "granular or O" types of agglutinins were developed about equally in the serum of cases of typhoid fever, while the agglutinins in the serum of vaccinated persons were mainly of the H type. Felix,¹⁷ who associated the O type agglutinins with immune body, failed to demonstrate such anti-bodies in sera from vaccinated men. Consequently he and his followers believe that our present typhoid vaccines are not likely to give adequate

protection. Experiments performed by Arkwright,¹⁸ in 1927, appeared to support this view of the importance of the O antigen, as he observed that guinea pigs were protected as well by vaccines containing only the O antigens as by others which contained both O and H antigens. However, Springut¹⁹ and Ibrahim, and Schutze²⁰ in vaccinating mice against *Bact. aertrycke* infection, obtained results which indicate that although the H antigen alone was of little immunizing value, the combination of H and O antigens was more effective than the O alone.

While the importance of the O type antigens is now generally recognized, there remains considerable doubt concerning the significance of O antibodies as indicators of protective immunity; and it appears that theories as to the supposed ineffectiveness of typhoid vaccines based on such reactions may be erroneous. This is suggested by such results as those obtained by Greenwood and Topley²¹ in experiments with mice vaccinated with various antigens of *Bact. aertrycke*. These investigators observed that, among those animals which were protected against infection by vaccines containing O antigens, only a minority developed O type agglutinins in detectable amounts. Whitehead²² in 1927 failed to demonstrate granular agglutinins in the sera of 6 out of 7 persons inoculated with the English Army vaccine, but he also obtained negative results with the sera of 12 typhoid convalescents. However, inoculation of the vaccine into rabbits was followed by production of granular agglutinins in large amounts. The fact that vaccination usually produces a higher O agglutinin content in the serum of rabbits than in man has been noted by many observers, including the authors, Cox,²³ and others. In spite of the speculation as to the possible significance of O antibodies, we have no proof that their titer indicates the

degree of protection afforded by typhoid vaccines and we concur in the following comment made by Topley and Wilson²¹ in 1931:

It would seem that circulating antibodies in very low titer or a heightened reactivity of the tissues to the O antigen afford an adequate degree of protection.

Another problem of considerable current interest is the question as to the relative effectiveness of vaccines prepared with the so-called "smooth" and "rough" types of typhoid bacilli. The investigations on bacterial dissociation, by Baerthlein²⁴ 1918, Arkwright²⁵ 1920-1927, and deKruif²⁶ 1921, gave evidence that certain of the many obvious cultural changes, which are to be observed among the descendants of a single pure strain of bacteria, may be associated with alterations in other important characteristics including physiological reactions, chemical and antigenic structure, virulence, etc. Arkwright²⁷ from his studies of the colon-typhoid-dysentery group, called attention to the fact that the so-called normal or "smooth" types of these organisms possess certain common characteristics, including: (a) the formation of typically round, domed, smooth, shining, translucent, non-granular colonies on solid media; (b) the development of a uniformly turbid growth in broth; and (c) the production of agar growths which form uniform suspensions in 0.85 per cent solution of sodium chloride. He observed that such smooth cultures might give rise to several different variants, of which the most important was the form designated as "rough." This so-called rough variant type is characterized by: (a) colonies which are dry, flattened, irregular in outline and surface, and coarsely granular; (b) by granular, precipitated growths in broth; and (c) by the fact that organisms from agar cultures spontaneously agglutinate in 0.85 per cent salt solution. Such S

to R dissociation is of considerable practical importance because, when complete, it is often accompanied by other changes including a decreased virulence, and by marked antigenic alteration in which the specific somatic O antigen of the smooth type is lost and is apparently replaced by a rough somatic antigen which may be common to several related species. As it has been shown that the smooth to rough, and the motile to non-motile types of variation may occur independently, or simultaneously, it is now recognized that motile organisms of the colon-typhoid group may conform to either of the following forms (1) smooth motile, containing both H and O antigens; (2) smooth non-motile containing O antigen but no H; (3) rough motile retaining H antigen but with the O replaced by R or Ø antigen; and (4) rough non-motile containing only the R or Ø antigen. The work of Zinsser and Parker²⁸ (1923), Furth and Landsteiner²⁹ (1928), White³⁰ (1928), etc., suggests that the S—R change in the typhoid-paratyphoid group may be associated with chemical alterations similar to those observed during the dissociation of pneumococci (Heidelberger and Avery³¹ 1923) (Reimann³² 1925). In other words, it seems possible (Zinsser³³) that the complete somatic antigen of the smooth type consists of two parts, a nucleo-protein common to all forms, and a soluble specific substance which alone produces no antibody but gives its specificity to the antigen as a whole, while the rough variants lose the SSS, retaining the nonspecific nucleo-protein antigen.

In vaccination experiments using guinea pigs and *Bact. paratyphosus* A, Arkwright¹⁸ observed that "smooth" vaccines protected against a subsequent test injection of living smooth organisms while "rough" vaccines failed. Similar, but less striking, results were ob-

tained with the typhoid bacillus. Likewise, in experiments with mice and *Bact. aertrycke*, various workers, including Springut,¹⁹ Ibrahim and Schutze,²⁰ and Greenwood and Topley,²¹ have also shown that vaccines prepared with rough cultures were much less effective than those made from cultures of the smooth type. In 1930 Grinnell³⁴ observed that vaccination of rabbits, and of man, with a rough sub-strain of *E. typhi* Rawlins produced little or no increase in the specific bactericidal power of the blood as compared with similar vaccinations with smooth typhoid bacilli. However, noting that the rough vaccine produced agglutinins for the smooth strains, he concluded that the agglutination reaction is not a satisfactory test for immunity, and that, in so far as bactericidal action is an index of resistance, rough strain vaccines are of relatively slight prophylactic value. Grinnell³⁵ (1932) made a study of 12 Rawlins cultures obtained from different laboratories engaged in making antityphoid vaccine, comparing them with freshly isolated smooth strains with respect to morphology, motility, colony form, nature of the growth in broth, growth in 10 per cent normal horse serum broth, and stability of suspension in normal saline solution. He concluded that 1 of these Rawlins strains corresponded in cultural and serological characteristics to the classical rough variant, and that the remaining 11 gave cultural reactions intermediate between the rough and smooth types; also that "in the stability of their suspensions in normal salt solution and in their agglutinability in the serum of rabbits immunized with non-motile smooth antigens—criteria on which Arkwright lays great stress—they corresponded to the smooth phase." However, he states that "as judged by the more significant tests of the bactericidal action of normal blood and by their virulence for mice, they should

be considered rough." Grinnell reported several experiments in which he observed: (a) that organisms from 18 hour broth Rawlins cultures were killed by quantities of fresh defibrinated guinea pig blood which had no bactericidal effect on the smooth cultures; (b) that when 0.1 c.c. amounts of 18 hour broth cultures were inoculated into mice, 95 per cent of those which received the smooth cultures died, while death occurred in only 3.3 per cent of those injected with the Rawlins culture; and (c) that a large proportion of mice, vaccinated with smooth strains, survived a subsequent intraperitoneal dose of a smooth culture, whereas most of those, vaccinated with a Rawlins strain, failed to survive this toxic dose.

Grinnell concludes from these experiments that

... since the Rawlins strain differs from the smooth phase of *Bact. typhosum* in cultural characteristics and in virulence, and is much less efficient than smooth strains as a protective antigen; ... it would seem but logical to substitute virulent smooth cultures for the very old Rawlins strain, if we are to expect the maximum protection from antityphoid vaccination.

This conclusion appears to us to be predicated entirely upon the assumptions (a) that the protective value of a typhoid vaccine can be measured by demonstrable antigen-antibody reactions; (b) that the infectivity for man of a typhoid culture is proportional to its toxic action when introduced into the peritoneum of a mouse; (c) that the degree of protection afforded a mouse against the toxicity of a strain is an index of the protection afforded man against natural invasion and infection with the same strain; and (d) that the Rawlins strain is a fixed entity irreversibly dissociated to a degree rendering it unfit for vaccine production, and that none of its sub-strains have been, or can be, maintained in a satisfactory dissociative state. On the other

hand, Maltaner³⁶ found that, measured by protection of rabbits against intravenous inoculations of living cultures, rough typhoid vaccines were distinctly superior to the smooth, even against smooth organisms. These results led him to the following conclusion:

Certainly the suggestion that smooth organisms be substituted for those of intermediate types, which have been most commonly employed, is not at present justified.

Such contradictory observations emphasize the fact that we still have no satisfactory laboratory criterion for determining the practical value of a typhoid vaccine, and leave unanswered the question of the relative merits of smooth and rough vaccines. Therefore, we propose to review the history of the U. S. Army Rawlins sub-strain and to look for evidence of dissociation both in the culture and in the practical experience with the vaccine. If this sub-strain has dissociated during the 25 years of its use, and if dissociation has significantly affected the protective action of the vaccine, then such alteration should be clearly reflected in the practical results obtained with the vaccine.

DISSOCIATIVE CHARACTERISTICS OF THE U. S. ARMY RAWLINS SUB-STRAIN

As indicated above, the Rawlins strain was isolated 33 years ago from the spleen of a fatal case of typhoid fever. After 4 years of cultivation on artificial media it was selected by Leishman for use in vaccines prepared for the British Army, because of its relatively low toxicity for guinea pigs, its satisfactory antibody production, and because of the fact that it formed a uniform suspension in salt solution. After the strain had been cultivated in England for a period of 8 years it was selected by General Russell for vaccine production in the U. S. Army.

Since its introduction at our Army Medical School, this Rawlins sub-strain has been maintained under conditions

which have probably kept its dissociative characteristics rather stable and uniform. The stock vaccine culture has been kept on agar slants, in sealed tubes, at refrigerator temperature; and at intervals of 20 to 30 days the cultures have been checked for purity and transferred to new media. For the production of vaccine, transplants are made from stock cultures to nutrient agar in Petri plates, and from these cultures about 12 typical colonies are selected for transfer to large, nutrient-agar slants, and to Russell's double-sugar media. After incubation, the cultures on double-sugar are tested with stock agglutinating serum containing both H and O agglutinins; and broth is added to the agar slant cultures. After several hours, the latter broth suspension of the "seed" culture is used for the inoculation of nutrient agar in Kolle flasks, which are then incubated at 37° C. for 24 hours. The organisms are then removed, suspended in buffered physiological salt solution, killed by heating in a bath at 56° C., and, after counting, 0.25 per cent cresol is added. The bacterial content is estimated with the Helber counting chamber, after which the vaccine is diluted to the desired concentration with 0.85 NaCl solution. The control tests carried out with each lot of vaccine include: (a) microscopic examination of unstained and Gram stained preparations, (b) various checks to rule out contamination and insure sterility, (c) the inoculation of mice, guinea pigs, and rabbits to detect abnormal toxicity, (d) study of the growth on agar to insure obtaining only "typical" colonies, (e) checks to avoid the use of organisms which produce a granular type of growth in broth or clump in physiological salt solution, (f) tests for agglutination with typhoid antiserum, and (g) tests for the production of a satisfactory agglutinin titer in rabbits inoculated with the vaccine. With a

few modifications noted below, this is essentially the technic followed since 1908.

The question will now be considered as to the classification of the U. S. Army Rawlins sub-strain in terms of Arkwright's criteria for smooth and rough dissociative types.

Colony Morphology—While the early records of the vaccine laboratory contain no detailed description of the morphology of the colonies, it is obvious that an attempt has always been made to select colonies of a uniform appearance since, from the beginning, it is recorded that only "typical" forms were used for the "seed" vaccine cultures. In Russell's³⁷ original records it is noted, at intervals, that "the most even looking" or "most uniform colonies" were picked; and at other times, it is stated that uneven growths appeared which had to be scraped off the agar, and that they were discarded. However, since most of the earlier texts on bacteriology described the typical typhoid colony as being of the "grape-leaf" or "veined" type on gelatin, it seems quite probable that, from the beginning, the U. S. Army Rawlins colonies have been somewhat irregular in outline. In this connection it is of interest to note that Arkwright²⁷ states that the veined or medusoid colonies, of the typhoid and paratyphoid groups, may have the same serological properties as those of the normal smooth colony.

During the past 5 years the colonies have been studied rather intensively; and an attempt has been made to select those more nearly conforming to the so-called smooth type. As a rule these colonies are not completely circular, showing some irregularity of outline, but otherwise they have the morphological characteristics of the smooth type. It should be added that while the criteria used routinely in the selection of colonies for use in the vaccine

have not been radically changed, it has been shown experimentally that it is possible to produce perfectly typical, smooth colonies with the U. S. Army Rawlins by various methods.

Suspensibility in Physiological Salt Solution—On rare occasions during the past 25 years, individual cultures of this strain have shown a tendency to agglutinate spontaneously in salt solution; but all such cultures have been discarded. Thus, throughout this period, there has been an unconscious but consistent selection of organisms possessing the smooth characteristic of uniform suspensibility in normal salt solution.

In recent experiments at the Army Medical School, it has been shown that both the Rawlins and a recently isolated, smooth, typhoid strain reacted similarly when suspended in NaCl solutions of 0.2, 0.4, 0.8, 1.6, 3.2 and 6.4 per cent. After incubation at 37° C. and at 50–55° C. for 19 hours, both strains remained in suspension; while a rough control strain (Dorset) showed clumping in salt solutions of 0.8 to 6.4 per cent.

Growth in Broth—For the reason given above, the character of the growth in broth has also been of the smooth type. While variants can be obtained which produce a granular growth in fluid media, such variants have not been used in the vaccine. When grown in nutrient broth media, containing 0.5, 1, 2, 3, 4, and 5 per cent sodium chloride respectively, there was no noticeable difference in the turbidity or sedimentation produced by the Rawlins and the recently isolated smooth strains; while a rough strain showed agglutination in all tubes within 24 hours.

Antigenic Structure—Since the beginning it has been an arbitrary requirement that the culture used for each lot of vaccine shall agglutinate, to a satisfactory titer, with a stock diagnostic antiserum; and that, when inocu-

lated into rabbits, the cultures shall produce agglutinins to a satisfactory titer. In more recent years it has been observed that the agglutinins produced in rabbits by U. S. Army Rawlins vaccines include both the H and O antigens. Livesay,³⁸ in unpublished experiments, has observed that with rough and smooth antisera the H and O antigens of this strain gave agglutination reactions similar to those obtained with smooth strains, including one recently isolated from a case of typhoid fever. As noted by Craig,³⁹ in 1929, individuals inoculated with the U. S. Army Rawlins vaccines may show in their sera other antibodies including precipitins and complement-fixing bodies.

Virulence—The original Rawlins strain was selected because of its relatively low virulence (toxicity?) for guinea pigs. Nichols⁴⁰ observed in 1915 that the U. S. Army sub-strain showed a relatively low virulence for guinea pigs and rabbits, but that it was distinctly toxic. We have no recent data concerning its virulence for man. However, Bulloch⁴¹ mentions two severe cases of typhoid which occurred "at the Royal Army Medical College in the vaccine department in workers who were employed in preparing vaccines with the old culture (Rawlins)."

It appears that the Rawlins sub-strain, as maintained at the Army Medical School, produces colonies which are slightly irregular in outline but do not conform to the morphological picture of a rough organism; and that in its other cultural, physical and antigenic reactions it behaves as a typically smooth organism. Furthermore, the records of the vaccine department indicate that there has probably been little change, in the dissociative state of this sub-strain, during the 25 years of its use.

At this point it may be well to warn against the present tendency to attrib-

ute fixed dissociative characteristics to any particular strain of organisms, without considering the environmental conditions to which it is exposed. While it is true that certain typhoid strains appear to have a greater tendency to variation than others, it is obvious that even such stable organisms as those descended from the original Rawlins culture are susceptible to such influences, and may be obtained and kept in either the motile or non-motile, smooth, intermediate or rough condition as desired. Among the many Rawlins sub-strains, which have been cultivated in different laboratories, it is possible to find some which are typically smooth in all their characteristics, many that are intermediate, and others that are entirely rough. In fact, sub-strains of the different types may be developed in any laboratory by a variety of methods. Larkum,⁴² for example, recommends for the production of smooth cultures, frequent intraperitoneal passage through guinea pigs. Others have obtained similar results by passage through other animals. Cox²³ has advised the use of Huntton's hormone agar for maintaining cultures in a smooth state. In unpublished experiments performed at the Army Medical School, Simmons⁴³ and Livesay³⁸ have shown that typical, smooth-type colonies can be obtained by various selective culture methods.

A most instructive example, of the ease with which a Rawlins culture may be altered, is furnished by the recent experience of Perry, Findlay, and Bensted⁴⁴ with the English Army vaccine strain. Cultures of this strain, examined by Whitehead²² in 1927, were of an intermediate-smooth type, with characteristics quite similar to those of the U. S. Army sub-strain. However, Perry, Findlay, and Bensted reported in April, 1933, that a culture of the English vaccine strain which they studied was extremely rough, having changed

both culturally and antigenically. Using Grinnell's technic for estimating virulence by mouse inoculation, it was found that this rough variant had a minimal lethal dose estimated at 500 millions, when compared with more recently isolated smooth cultures, including an Indian strain, "Allahabad," which was lethal in doses of 40 millions. They observed that this rough Rawlins culture "failed consistently to protect mice against a subsequent lethal dose of a virulent strain of *Bact. typhosum*, whereas a series of mice previously inoculated with a vaccine manufactured from a recently isolated virulent strain were effectively protected against a similar test dose." Incidentally it was noted that, even though the smooth strains had been recently isolated, careful colony selection was necessary, due to the fact that the usual rough variants were constantly encountered; also that, while vaccine prepared from the Allahabad smooth strain were most effective, the vaccine made from its rough variant gave almost as satisfactory results. The authors concluded that, in view of Grinnell's work, and of their own investigation, they were "of the opinion that the Rawlings strain should be discarded and the strain Allahabad substituted for it in the Army typhoid-paratyphoid vaccine."

However, it is of interest to note that within a few months' time the same authors⁴⁵ published a second report in which they observed that, while most workers acquainted with the Rawlins typhoid bacillus are in agreement as to the predominance of its rough character, they had recently received two cultures of the strain, both of which produced definite smooth colonies, which were antigenically pure and showed little or no tendency to throw off rough variants; also, that the virulence of these smooth Rawlins sub-strains was in sharp contrast to that of their rough Rawlins culture. Moreover, they re-

ported that they had since rejuvenated their rough Rawlins culture by simply passing it through mice in doses just sufficient to kill in 24 to 48 hours. Cultures from the heartblood of such animals yielded profuse growths of pure smooth colonies, and these organisms consistently killed mice in a dose of 40 millions. Their comments on this smooth Rawlins culture follow:

It is now apparent from the mouse experiments that have been detailed that rejuvenation of this senile strain can be effected by certain *in vivo* methods. By such methods the original Rawlings strain has been so transformed that its virulence is possibly of a higher degree now than when it was originally employed as a typhoid vaccine. At the present time it is not possible to state how permanent this change may be; no alteration in this respect, however, has been noted during the last 2 months. *It has also been ascertained that this smooth Rawlings strain is as effective in protecting mice as any of the more recently isolated strains with which we have worked* (Italics ours). Possibly, further investigation may prove its superiority in this respect, and these comparative estimations are in progress. *It is, however, questionable whether so highly virulent an organism is suitable for inoculation into man* (Italics ours). In addition to the criterion of its protective properties, antecedent experience should prove that its administration is not followed by severe after-effects. The strain of typhoid bacillus (Allahabad) at present included in the Army vaccine was subjected to extensive trials, both from the protective and reaction aspects, before its selection was approved. Until such time as more experience is obtained of the after-effects of the inoculation of this smooth Rawlings strain into man it is not proposed to include it in the typhoid-paratyphoid vaccine.

This experience with the English Rawlins vaccine strain indicates quite clearly that, by a single passage, even a very rough culture can be transformed into a smooth type which is virulent for mice, and effective in Grinnell's mouse protection test. It also indicates that if "smoothness" and "roughness" are to be held as important criteria for the selection of vaccine strains of

the typhoid bacillus, our practical problem is not so much concerned with the search for recently isolated cultures as with the question as to what dissociative state is desirable, and what methods are most suitable for the maintenance of our present culture in the most effective condition.

Since the question as to what constitutes the most desirable dissociative state has not been satisfactorily answered by laboratory tests, the following analysis of the practical results obtained with typhoid vaccination in the U. S. Army and Navy should be of considerable interest as a practical approach to the possible solution of the problem.

The ideal method of determining the relative effectiveness of a typhoid vaccine would be to administer virulent typhoid bacilli by mouth to large groups of vaccinated individuals; but such experiments are not practicable. Consequently the best information available is afforded by statistical studies dealing with the incidence of typhoid fever among vaccinated persons.

Before proceeding with the statistical analysis it should be noted that on several occasions vaccinated individuals have accidentally swallowed living typhoid bacilli without developing typhoid fever.

LABORATORY EXPOSURE TO INFECTION

In a case observed by Grant⁴⁶ in 1921, an assistant in the 8th Corps Area Laboratory sucked into his mouth 0.5 c.c. of a heavy suspension of living typhoid culture, strain K110. His mouth was washed out with 50 per cent alcohol and he was given 0.5 c.c. of Army vaccine. Four days later he developed headache and malaise, but there was no fever, or other symptom, except slight headache on the 8th day. Typhoid bacilli were isolated from the feces on the 12th day after the accident, and again on the 3 succeeding days,

but none were found in the blood. This man had received the U. S. Army vaccine 14 months previously.

In 1922 Sergeant George F. Luipold, while working in the vaccine department at the Army Medical School, swallowed about 25 c.c. of a saline suspension of the U. S. Army Rawlins culture containing about 3,000 million organisms per c.c. After rinsing his mouth with a cresol solution and with alcohol, he was given a subcutaneous injection of vaccine and kept in bed for 1 week. Cultures of stool, urine, and blood taken during this week were negative. On the 4th day he developed a temperature of 101 which disappeared after 2 days, but aside from a sore throat there were no other symptoms. Prior to this accident, the Sergeant had received 3 complete courses of Rawlins vaccines, the last in 1920.

THE U. S. ARMY VACCINE AND TYPHOID FEVER

We know of few convincing data bearing directly upon the effectiveness of antityphoid vaccination. Many of the available data are from the British experience in the Boer War, which was with a vaccine now known to have been faultily prepared. When universal compulsory vaccination was introduced in

If the curve fit perfectly, all dots would fall upon the line.

the United States Army and Navy, obviously there were no controls. Therefore, the only approach to the question of the effectiveness of our vaccine lies in an inquiry into the effectiveness of the control of typhoid and paratyphoid fevers before and after the advent of the vaccine.

Mortality from typhoid fever has been declining in the civil population of the United States since about 1900. The Registration Area of 1900 comprised the states of Connecticut, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island, Vermont, and the District of Columbia. It would be difficult to select another comparable area in the United States where public health agencies were better organized and supported; and the experience of this area will be accepted by most observers as representing an experience decidedly above average in effectiveness in the control of typhoid fever by sanitation.

The mortality from typhoid fever in the Registration Area of 1900 (less the District of Columbia), from 1890 to 1932, is shown in Figure I. A logistic curve, with 4 times the probable errors of its ordinates, has been fitted to the observations from 1900 on. The fit is remarkably good and this curve can be accepted as indicating the trend of typhoid mortality in this area between these dates. The trough during the

90's need not concern us; it may be due to indifferent reporting (since a large part of the area was not then in the Registration Area), or it may be due to unexplained events in the natural history of typhoid fever. The important facts are: (a) that typhoid fever was at a certain level of incidence in 1900, and (b) that this level has declined since that time in a surprisingly orderly fashion. The fit of this curve is better shown, perhaps, by Figure II.

The equation of the logistic curve is $y - d = \frac{K}{1 + Ce^{rt}}$. This says, in simple language, that the upper and lower limits of the variable y are K and d , respectively; the rate of variation of y is expressed by r as the exponent of the Napierian e , and t (time) expresses the duration of the influence of r .

r , then, is the inherent rate of change of y . Consequently, in this case, r is the index of the influence of *all the factors* tending to reduce the mortality from typhoid fever. Since this curve fits very well throughout the range 1900-1932, and the value of r remains constant (0.1492966), the sum of the influence of all the factors tending to reduce typhoid mortality in this population has not changed significantly since 1900. It is conceivable, but scarcely probable, that different factors, exerting exactly the same amount of influence, were substituted from time to time. The most logical inference is that the same factors were in play in 1930 as in 1900, and that these were improvement of water supplies, sanitary sewage disposal, and possibly improvement in the personal and occupational hygiene of food handlers.

Now there is some indication that at least one other factor was introduced around 1920. The best fitting curve for the observations from 1900 to 1921 appears to be one asymptotic to 0.015 (deaths per 1,000), or $d = 0.015$. The curve shown in Figure I is asymptotic

to zero. This difference is, so far, too small to be regarded seriously. It *may* represent the effect of the increasing use of vaccines among the civil population.

In any event, whatever r may represent, mortality from typhoid fever in the Registration Area of 1900 has declined in the past 30 years in a regular and orderly fashion that is satisfactorily expressed by a logistic curve, and this curve may be accepted as the measure of typhoid fever in a representative civil population provided with health agencies above the average in accomplishment.

The incidence of typhoid and paratyphoid fevers in the U. S. Army from 1890 to 1932 is shown in Figure III.

FIGURE III

Admission Rates, Typhoid and Paratyphoid Fevers, All American Troops, U. S. Army, 1890-1932

The smaller population, the variations in exposure due to war, mobilizations, geographic distributions of troops, etc., and the possible effect of immunity acquired by attacks of the disease—these all contribute to the irregularity of the line. Paratyphoid fevers were not distinguished from typhoid until 1911; so the inclusion of all enteric fevers gives a more accurate picture. The sharp peak in 1916 is largely paratyphoid. In Figure IV it will be seen that the typhoid incidence of that year was less than 0.6 per 1,000.

In order to smooth these peaks, 3 year average incidence rates, centering

FIGURE IV

Admission Rates, Typhoid Fever Only,
U. S. Army and Navy, After Introduction
of Typhoid Vaccination

upon each year, are shown in Figure VI. Merely to place the curve where comparison is easiest, and not to suggest case fatality rates, the Registration Area curve $\times 18$ is plotted in this graph. It is evident that the curve expresses fairly well the trend of typhoid in the Army from 1891 to 1908 (the Spanish American War excepted) and in the Navy from 1898 to 1910. Since 3 year average admission rates are used, the effect of the introduction of vaccine is spread over some 5 years, but, even so, the decline in both the Army and Navy is very sharp.

It is to be expected that the advances in sanitation in the military services kept pace with civil improvements. It has been argued that military sanitation has advanced much more rapidly than civil sanitation and that this largely explains the sharp decrease in incidence of the enteric fevers in the Army and Navy in 1911-1912. Aside from the fact that no one knows of any radical innovations in military sanitation adopted at that time, this argument would be much more convincing were the sources of typhoid fever among soldiers to be found only within the sentry lines. As a matter of fact, within recent years at least, the only demonstrable sources of infection have been

outside military control, so that the status of typhoid in the civil population is a fair index of the exposure of the soldier to infection.

During war, and in large concentration camps, this index is unquestionably faulty, but the greater part of our experience with typhoid vaccine has been in small garrisons in time of peace. Those who attribute the sudden drop in incidence in 1911 for the Army and 1912 for the Navy wholly or largely to improvements in sanitation, exhibit a naïve ignorance of the history of typhoid fever in the military services. The experience of the Spanish American War resulted in immediate stressing of the importance of sanitation. Chlorination of water supplies was commenced shortly thereafter, but this practice was extended gradually and relatively slowly. Why the improvements in sanitation should exhibit such a cumulative effect and select the years immediately following the introduction of vaccine to become so prominent has never been explained by critics of vaccination.

Finally, if the vaccine has exerted any influence upon the incidence of typhoid fever in the military service, radical changes in the vaccine itself, or the method of administration, must be reflected in the admission rates for this disease.

It is unnecessary to defend the assertion that the law of diminishing returns operates in the control of typhoid fever. This is to say that, as the incidence of the disease approaches the vanishing point, greater efforts are required to

FIGURE V

Admission Rates, Paratyphoid Fevers Only,
U. S. Army and Navy, After Introduction
of Typhoid Vaccination

FIGURE VI

Trends of Typhoid and Paratyphoid Fevers, U. S. Army and Navy and Registration Area of 1900 (Less District of Columbia), 1891-1931

effect further reduction. It is a fairly safe prediction that it will require more time and effort to eradicate the final death per 100,000 per annum than it has required to reduce these deaths from 30 in the Registration Area of 1900 to a single one, if such an effort can ever be justified economically.

It is to be expected then, that, all other things being equal, the effect of vaccination will be less and less evident as typhoid fever declines in incidence from other measures of control. Figure VII shows the ratio of admissions for typhoid fever in the Army and Navy to deaths from typhoid fever in the Registration Area of 1900 (less D. C.) for 4 different periods. Paratyphoid fevers were not distinguished from typhoid in the military services until after vaccination was introduced. But, since the mortality from paratyphoids is much less than from typhoid, it is necessary to subtract them from the admissions in order not to exaggerate the effect of the vaccine. Omitting the Army's epidemic year of 1916, 83 per cent of all admissions for enteric fevers from 1911 to 1932, in both services were for typhoid fever; and the proportion is surprisingly constant. In order that any error might be on the side of conservatism, for the admissions in the Army and Navy from 1902 to

1909, 20 per cent were deducted as having probably been paratyphoid fevers.

For this period just prior to the introduction of the vaccine, based upon such an estimate, there were approximately 17 admissions for typhoid fever in the Army and Navy for every death from typhoid fever in the Registration Area of 1900 (per 1,000 exposed to risk in each case). Had the control of typhoid fever in the military services and the civil population proceeded apace, this ratio would remain constant; but in the 8-year period immediately following the introduction of the vaccine, this ratio dropped to 1.67 admissions from the Army and 2.55 admissions from the Navy to each death in the Registration Area. This means that, following the introduction of the vaccine in the military services, typhoid control became 9 times as effective as it had been just before; and this improvement took place largely in less than 2 years. Also, it will be remembered that this comparison takes into

FIGURE VII

*1913 for Navy

account the rapid decline of typhoid fever in the Registration Area during these periods.

In the next period, 1920-1925, there is again a slight advantage for the military services, the ratios for the Army and Navy declining to 1.54 and 2.12, respectively—this despite the fact that the incidence of the disease was rapidly approaching zero in the services and control measures were therefore, less productive of quantitative results.

In the final period of the experience, 1926 to 1932, typhoid fever declined some 56 per cent in the Registration Area. In the Army, the incidence increased from 0.063 to 0.090 per 1,000, while it remained stationary in the Navy (0.087 to 0.084). This resulted in an increase of the ratios of admissions in the military services to deaths in the Registration Area to 5.00 and 4.67 for the Army and Navy, respectively.

In brief, Figure VII shows that typhoid control was decidedly more effective in the military services than in the Registration Area of 1900 for the period 1912-1919; that it was even slightly more satisfactory in the 6 years following, but that something happened to typhoid control in the military services in the 1926-1932 period.

It will be shown later that a radical change was made in the vaccine just prior to this last period. We believe this reversal of the trend of the control of typhoid fever in the military services, following the alteration of the vaccine, to be the most convincing evidence of the rôle played by the vaccine in the control of the disease. Admitting that military sanitation has progressed since 1911, admitting for the sake of argument only that this has been solely responsible for the great reduction in typhoid fever, who will now advance the argument that military sanitation has gone backward since 1924? There have been no wars nor even mobilizations in this period.

The vaccine was changed; and this change has been reflected in the typhoid experience of both the Army and Navy.

MODIFICATIONS OF THE VACCINE

From the time of its introduction until July, 1917, the vaccine consisted of a saline suspension of the Rawlins strain, grown upon beef-extract agar, and killed at 53°-54° C. for 1 hour. The vaccine was standardized at 1 billion organisms per c.c. by the Harrison method in which washed red blood cells were used for comparison. Later experience has shown that the actual bacterial count is only about one-half that of the count estimated by this method, so that during this period the vaccine consisted of approximately 500 million typhoid organisms per c.c.

In July, 1917, 750 million paratyphoid-A organisms, and a like amount of paratyphoid-B, were added to the vaccine, by the same Harrison method of counting which resulted in a vaccine that, by actual count, approximated 500 million typhoid and 750 million paratyphoid organisms.

In July, 1919, the direct method of counting in a Helber chamber was adopted which resulted in doubling the quantities of each of the components of the vaccine; and in April, 1920, the nephelometer method of counting was introduced, using standards established by counts in a Helber chamber.

These nephelometer standards became more and more opaque with age, resulting in higher and higher counts in the vaccine, a fact that was not recognized until some time in 1923. Meanwhile, the reactions had become so severe that in February, 1922, the paratyphoid constituents were reduced to 500 millions each—by the nephelometer estimate, which was still inaccurate, and actually there remained almost 1,500 million paratyphoid organisms per c.c.

The concentration of the vaccine continued to increase with the age of the

standards until, when checked with the Helber chamber late in 1923, the actual count was found to be approximately 1,750 million typhoid and a like amount of paratyphoid organisms per c.c.—a total count of around 3,500 million organisms per c.c., although the prescribed strength was only 2,000 million. The severe reactions again forced a reduction in the strength of the vaccine and, in March, 1924, the vaccine for the Army was re-standardized by direct count with the Helber chamber at 500 million typhoid, 250 million para-A and 250 million para-B organisms per c.c. At this time the Navy discontinued the paratyphoid fraction and their vaccine was standardized at 1,000 million typhoid organisms per c.c. Two other changes were made at about the same time: veal infusion agar was substituted for the beef-extract media and the killing point was increased to 56° C. for 1 hour.

In October, 1927, the Army vaccine was again modified by discontinuing the para-B fraction and increasing the typhoid fraction to 750 million per c.c.

Based upon the physical characteristics and method of production, the total experience with the Army typhoid vaccine falls into three more or less homogeneous periods: (1) From 1911 to July, 1919. During this period, with the exception of less than 2 years during the World War when the paratyphoid fractions were first added, the vaccine consisted of about 500 million typhoid organisms per c.c. (2) From July, 1919, to March, 1924. In this period the dose was greatly increased by design and continued to increase for the reason set forth above. (3) From March, 1924, to the present. In this period the dose was reduced, the method of preparation was slightly changed, and the proportion of the constituents of the vaccine for the Army was again altered in 1927.

The most radical changes in the vac-

cine have been in the concentration of the antigen although it is recognized that these may have affected the protective value less than the change of media and the raising of the killing point. It will be seen, however, that a great decrease in the incidence of typhoid and paratyphoid fever followed the increase in dosage of vaccine prepared exactly as before.

FIGURE VIII

Trends of Typhoid and Paratyphoid Fevers, U. S. Army, With Relation to the Composition of the Vaccine

In Figure VIII is plotted: (a) the approximate strength of the vaccine from 1911 to 1932, and (b) the trend of typhoid and paratyphoid fevers in the corresponding periods. A lag of approximately 1 year has been allowed after each major change in the vaccine in order to afford the new vaccine an opportunity to show its effect. The trend is shown, in each case, by a straight line ($y = a + bx$) fitted to the observed incidence rates.

The influences of the border epidemic of 1916 and the World War are exerted toward the end of the first period so that the trend was decidedly upward from the low rates of 1912 to 1915. The strength of the vaccine was low during almost all of this period, and the demands upon the vaccine in 1916 and the World War were much greater than during the garrison days of 1912 and 1913. Extrapolation of a straight line is, of course, decidedly unwise; and it must not be inferred that a continuation

of the World War would have resulted in an increasing amount of typhoid fever. The evidence is to the contrary, it appearing probable that the incidence of enteric fevers approached the peak in 1919. It is evident, however, that the vaccine of that day was inadequate for the maintenance of as low a rate under field conditions as under garrison conditions, although, based upon past experience, the typhoid rate during the World War was phenomenally low, and generally considered satisfactory.

During the second period (1920-1925), characterized by garrison environment and a very strong vaccine, paratyphoid fevers disappeared from the Army, and typhoid approached the vanishing point. The trends of both were decidedly downward with the increasing strength of the vaccine.

The environmental conditions of the Army during the third period were not significantly different from those during the second. In this period, paratyphoid began to appear (see Figure X) and the level of the incidence of typhoid was higher. The trend, measured in this manner, is slightly downward, but this must be accepted with considerable scepticism since the very favorable years of 1930 and 1932 may not be quite representative. The Navy trend is upward during this period.

The Navy experience, shown in Fig-

ure IX, is very similar. The Navy, possibly by reason of the similarity of hygienic conditions in war and peace, has escaped the epidemics of the Army. Actually, the personnel of the Navy probably are less exposed to the enteric infections in war than they are in peace. The trends of both typhoid and paratyphoid fevers in the first period are downward. In the second period, the rates of decrease are faster than in the first period, while there is a rise in both typhoid and paratyphoid fevers in the third period.

FIGURE X

Trends of Paratyphoid Fevers, U. S. Army and Navy, 1926-1932. During this period the Navy vaccine contained no paratyphoid organisms while the Army vaccine retained a paratyphoid fraction.

These widely separated experiences are in complete agreement and indicate (1) that the low dosage of vaccine from 1911 to 1919 was sufficient to effect a marked reduction in the incidence of typhoid fever, especially under garrison conditions; (2) that the very large doses of vaccine from 1919 to 1924 greatly reduced the incidence of enteric fevers, and this reduction progressed as the vaccine dosage increased through ageing of the standards; and (3) that the reduction of the dosage of the vaccine in 1925 was followed by an increase in the incidence of enteric fevers, but the level has remained appreciably lower than during the 1911-1919 period when the dosage of vaccine was least.

There is another significant reversal of trend shown in Figure VII. So long as the same vaccine was furnished both

FIGURE IX

Trends of Typhoid and Paratyphoid Fevers, U. S. Navy, With Relation to the Composition of the Vaccine

the Army and Navy, there was more typhoid fever in the Navy than in the Army. Since the dose of the typhoid fraction was reduced in 1925 in the Army to 500 million and in the Navy to 1,000 million, there has been less typhoid in the Navy than in the Army. This is also illustrated very well in Figure IV.

THE EFFECTIVENESS OF THE PARATYPHOID FRACTION

Nichols⁴⁹ once said that "clinical experience is unanimous that there is no immunity to the paratyphoid infections after typhoid immunization." Clinical experience is, however, notoriously unreliable.

Before the addition of the paratyphoid fraction to the vaccine, there was one epidemic of paratyphoid fever in the Army (1916). This was, however, during a period in which the dosage of the typhoid vaccine was, as is now known, entirely inadequate. Paratyphoid fevers declined in incidence in the Navy before the paratyphoid fraction was added to the vaccine, and, *since the paratyphoid fraction was dropped from the Navy vaccine, paratyphoid fevers have increased less rapidly than typhoid fever in that service.* They have also increased less rapidly than has paratyphoid fever in the Army (see Figure X), which retained a paratyphoid fraction. However, we commend these figures to you with reservations, since there are too few years in which there was any paratyphoid in the Army to make the trend entirely significant.

It is our opinion that the experience suggests that a potent typhoid vaccine may control paratyphoid fever, and that there is no evidence that the reverse is true to the same degree. We feel that, if any reduction of dosage must be made because of toxicity, this reduction should be entirely in the paratyphoid fraction. Further experience

with increased dosage of a monovalent vaccine may lead us to change our opinion.

SUMMARY

The experience with the Army Medical School vaccine has been divided into the periods corresponding to major changes in the production of the vaccine.

During the first two of these periods only the dosage of the vaccine was changed. In the third period the dosage was decreased and, also, the medium used for growing the organism and the temperature at which the vaccine was killed were changed. Any effect of change of media and killing-point cannot be separated from the effect of the reduction of dosage but, from the experience of the first two periods, it would appear that the reduced dosage alone accounts, in whole or in large part, for the increased incidence of enteric fevers in the last period.

Studies of the dissociative characteristics of the U. S. Army sub-strain of the Rawlins culture show that this organism, as used for the production of vaccine, forms an irregularly shaped colony but, otherwise, possesses all of the characteristics of a typical so-called smooth type of organism. Furthermore, the available records indicate that, if there has been any dissociative alteration in this strain since it was brought to the Army Medical School in 1908, it has not been toward roughness. As a matter of fact, there is no laboratory or statistical evidence of any dissociative change. The only indication of decreased effectiveness of the vaccine can be satisfactorily explained on the ground of dosage alone. *The Rawlins strain may not be the best typhoid vaccine strain; but it is our belief that the Army Medical School sub-strain is no worse today than it ever was.* Nor has it been proved that the present state of this sub-strain is

not the optimum for the prevention of typhoid fever in man; or that, when the optimum dissociative state has been determined, the Rawlins strain cannot be so maintained.

In view of these facts, we believe that the Army vaccine can be improved by increasing its bacterial content within the limit of safety.

NOTE: The authors wish to acknowledge the assistance rendered by the staff of the Department of Laboratories, Army Medical School, particularly Major H. R. Livesay, M.C. and Captain F. E. Council, M.C.; and are likewise indebted to Lt. Col. George L. Lull, M.C., of the Statistical Division of the Surgeon General's Office, and Major Virgil H. Cornell, M.C., Curator of the Army Medical Museum.

A New Life Table for the City of New Haven

J. H. WATKINS, PH.D.

Department of Public Health, Yale School of Medicine, New Haven, Conn.

IN 1918 Dublin¹ presented a life table for New Haven, Conn., based upon the population of 1910 and upon the deaths of 1909, 1910, and 1911, with the statement:

It is hoped that the figures as now prepared will be repeated for the 3 year period centering around 1920, and that the work now being carried on by the health authorities of New Haven will be reflected in a material reduction in mortality, with a corresponding increase in the expectation of life.

A new life table for New Haven 20 years later is here given for comparison with that of Dr. Dublin. The population of 1930 and the deaths (by 5 year age periods) of the 3 years 1929, 1930, and 1931 were used. The table was constructed according to Grove,² who has presented the construction of the short form of a life table in complete detail in order that it can be followed by health officials in making tables of their own. In order to obtain figures

for age-periods comparable with those given for the earlier table, the method of osculatory interpolation was used.

The expectation of life at birth in 1929-1931 was 60.65 years. The maximum expectation of life, 62.76 years, was found for the beginning of the second year. At age 10 the average length of life remaining was 55.15 years; at age 20 it was 45.90 years; at age 45, 24.59 years; at age 60, 14.19 years.

The new table is not entirely comparable with that of Dr. Dublin due to the fact that the Connecticut Bureau of Vital Statistics has allocated deaths to place of residence since 1926. However, non-resident deaths and deaths of residents dying elsewhere in Connecticut, New York, and Massachusetts were available for the year 1931, and from these, non-allocated deaths for the 3 years were estimated. The expectations of life calculated from these deaths were, of course, lower than those obtained from the allocated deaths. At birth the expectation of life was 57.86 years, a decrease of 2.79 years from the allocated expectation of life. This figure, compared with that given in Dr. Dublin's table for 1909-1911 (49.37) shows an increase of 8.49 years, for the two decades, in the expectation of life.

Table I indicates a vast improvement in conditions affecting mortality, some credit for which can be reasonably attributed to the effects of the work of the New Haven Depart-

TABLE I

EXPECTATION OF LIFE

Years	1909-1911	1929-1931	1929-1931
	<i>Unallocated Deaths</i>	<i>Unallocated Deaths</i>	<i>Allocated Deaths</i>
0	49.4 years	57.9 years	60.6
1	54.6	60.4	62.8

60	12.9	13.4	14.2
70	8.5	8.6	9.0

ment of Health and other health agencies in the city. Under the leadership of Dr. John L. Rice, Health Officer for the past 10 years, the health organizations have consistently displayed a high order of efficiency, shown by the fact that New Haven has twice won and once shared first place in the Inter-

chamber Health Conservation Contest for cities in her population class.

The use of life tables for measuring mortality has been restricted in public health circles due to the difficulties of construction. These difficulties should not prevent their use for cities of at least 150,000 population, especially in

view of the fact that health officials may shortly have to resort to the expectation of life in order to demonstrate improvements in conditions affecting mortality. A declining birth rate, restricted immigration, and the subsequent aging of the population may in time cause the death rate to remain stationary and then to rise (Fairchild). When this occurs a crude mortality rate will obviously be of no value in demonstrating changes in mortality, and for

this purpose should be abandoned. The expectation of life is not affected by such changes, and as a more accurate index of mortality, will slowly but certainly come into wider use by health officials.

State Board Number of the Journal of the American Medical Association

THE annual report of licensure statistics,¹ prepared by the Council on Medical Education and Hospitals of the American Medical Association, is replete with valuable information regarding the progress of medical education, as well as the different forms of licensing procedure. It bears the stamp of accuracy and in this no doubt the executive officers of the different state boards have had an important part.

While distinct advance has been made in the requirements for licensure, there are still a number of states in which the licensure requirements are not equivalent to those of graduation from recognized medical schools. In four states: California, Connecticut, Mississippi and Pennsylvania, only one year of premedical college training is required, and in the five states of Delaware, Massachusetts, Missouri, Nebraska and Ohio, high school graduation or its equivalent constitutes the preliminary education requirement. One year of intern service is now required by nineteen state boards. It is also noted that in nine states 84 graduates

of unapproved medical schools were registered, and in six states 58 osteopaths.

In the interest of interstate endorsement, it is to be hoped that statutory changes will be made in the states concerned, so that medical licensure will be placed on a uniform basis. Present conditions in these states permit registration of individuals having distinctly inadequate training for the practice of medicine.

In only twenty-nine states is naturalization a requisite for licensure. Certainly citizenship should be an essential qualification for the practice of medicine in all the states.

The increased number of candidates who are added to the profession annually is discussed in the interesting editorial by Dr. William D. Cutter,² which presents the real crux of the existing medical economic situation. — *Federation Bulletin*, Federation of State Medical Boards of the United States, 20, 5 (May), 1934.

Metal Tank for the Preparation of Mass Cultures of Anaerobic Bacteria

CHARLES WEISS, PH.D., M.D., AND EDWARD J. CZARNETZKY, PH.D.
Research Laboratories, Mount Zion Hospital, San Francisco, Calif.

IN attempting to prepare large quantities of protein fractions from anaerobic bacteria it became necessary to cultivate these organisms on a large scale. The anaerobic jars which are available on the market are usually made of glass and hence breakage is frequent. The phospho-bronze apparatus devised by Wilson¹ is rather small and expensive, the cost being about \$60. For these reasons the jar shown in Figure I was devised. It is made

These cookers are provided with steam-tight fitting lids which are held down by means of several locking bolts supplied with winged nuts and screws, thus making the use of gaskets unnecessary. The retort, or body, is also of pure cast aluminum.

In order to convert these utensils into anaerobic jars, it is necessary to remove the safety or control valve, the steam pressure gauge, and the petcock or release valve. This leaves 3 threaded

FIGURE I. Details of lid of anaerobic jar and special wrench for winged nuts

from a cast aluminum pressure cooker, which is available in convenient sizes ranging from 10 to 25 qt. capacity.*

openings in the lid. Into 2 of these holes are inserted 2 nickel plated hose cocks (No. 746, $\frac{1}{8}$ " pipe).† A piece

† Manufactured by the Roberts Brass Manufacturing Company, Detroit, Mich.

of 4 mm. glass tubing, extending 2" above and 1" below the surface of the lid, is inserted into the third or central opening. This tube is sealed in place with Metallic-X cement and covered with an inverted 13 mm. test tube which is cut down to 7.5 cm. A redox indicator, such as methylene blue, is poured into the inverted test tube through the tube. The other 2 hose cocks in the lid are also sealed with this cement.

The jar has been found satisfactory when used in the phosphorus method of Varney,² or the hydrogen displacement method of Novy,³ or in conjunction with a central catalyzing station such as that described by Boëz⁴ and Cohen.⁵ Among the anaerobic organisms which have been successfully cultivated in this apparatus are *Bact.*

pusiformis, *Bact. melaninogenicum*, an anaerobic streptococcus, *C. welchii* and *C. perfringens*.

For the sake of economy, flat, 8 oz. bottles (obtained at all pharmacists as containers for "Rub-alcohol") are used in place of Blake bottles, when surface growth on solid media is desired. The total cost of the apparatus made from an 18 qt. pressure cooker does not exceed \$22.

Modern Trends in Public Health Administration County Health Work *

JOSEPH W. MOUNTIN, M.D.

Surgeon, U. S. Public Health Service, Washington, D. C.

THE early county health organizations were developed for the purpose of bringing modern public health service to people living in villages and in open country. More recently the importance of the county in the scheme of government has become recognized by students of government and by public officials; consequently the county is being utilized more and more in the administration of many public services; such as, health, education, welfare, and highways for the contained cities of the county, as well as the rural areas.

Many additional influences are tending to bring urban and rural people closer together and to minimize their supposed differences. It is, therefore, no longer correct to separate all people into urban and rural groups or to consider their health problems as being fundamentally different.

Those responsible for arranging this symposium were well aware of these facts, but since other papers deal with health administration from the standpoints of the state health department and the large cities, it was deemed best for me to discuss trends in health administration having a special bearing on problems peculiar to the smaller cities and rural areas and to indicate

how the county is being utilized as a unit of government for the administration of public health service.

TREND IN ORGANIZATION

The earliest official health agency was the board of health. In the eastern and the north-central sections of the United States, these boards were organized on a township basis. County boards were organized in other parts of the country. As a rule, when villages or boroughs attained any considerable size, they chose to administer their health affairs separately, but in a similar manner. The early boards of health were created primarily to control epidemics. Not infrequently the board employed a layman on a part-time basis whose functions for the most part were confined to quarantine, disinfection, and the abatement of nuisances. The southern and western boards appear to have favored the employment of part-time physicians who also rendered medical service to the county poor and to inmates of the county jail and the almshouse. As one might expect, organizations of such primitive types could not be adapted to the needs of the modern public health movement.

In those urban sections where the board of health remained engrossed in its original functions, the newer elements of the public health program were developed by other agencies. The school system soon began to furnish at

* Read before the Health Officers Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

least a minimum amount of health supervision for children of school age; programs for maternity or infancy hygiene frequently were sponsored by community nursing organizations; and voluntary agencies often became active in special fields, particularly tuberculosis. For a number of years, these supplementary services were to be found in cities and industrial areas, and little or nothing was being done in farming sections.

The modern public health movement of the rural villages and open country was not of local origin; it came as a result of stimulation and financial aid from outside sources. Among the agencies which took an early and prominent part in promoting the basic administrative organization were the U. S. Public Health Service and The Rockefeller Foundation. The tuberculosis control movement was closely identified with the National Tuberculosis Association. The American Red Cross was a leader in the field of rural public health nursing. The incorporation of infancy and maternity hygiene in local programs can in a large measure be credited to the U. S. Children's Bureau operating under the Maternity and Infancy Act. The Commonwealth Fund and the Milbank Fund followed by demonstrating the need for something more than a skeleton type of organization. These and other health agencies worked through and with the state health departments. A number of the state health departments, notably in the South, set out very early to induce the county authorities to accept some degree of responsibility for administering and financing local health service.

There is some dispute as to the location of the first county health department, but the movement proper appears to have begun almost simultaneously in the States of Washington, North Carolina, and Kentucky, in 1911. It

gradually extended and seems to have reached its high water mark, for the present at least, in 1931, when 616 counties or comparable districts were receiving service which was organized under the direction of a whole-time health officer. Kentucky had the largest number of counties, namely 81, under this type of service. Delaware led in the percentage of rural population under whole-time health service, each of its 3 counties having been provided with a local whole-time health organization by the state. Of the states in which the local governmental units maintained the health organizations, with or without assistance from the state health department or other sources, Maryland, with 95.3 had the highest percentage of rural population under whole-time health service.

The total number of county or district health organizations decreased to 581 at the end of 1932. A large part of this recession can be attributed to the termination of special county-wide organizations created to meet emergencies caused by floods and droughts in the valley of the Mississippi and its tributaries. While the figures for the present calendar year will not be compiled until the close of the year, fragmentary information coming to the Rural Sanitation Office of the Public Health Service indicates that a number of departments are either being discontinued or forced to operate on curtailed budgets, due presumably to adverse economic conditions and to the withdrawal of aid from state and other extra-county sources.

An analysis was made of 532 health organizations which in 1932 were serving 581 counties or comparable units of population. In 29 of these county or district health organizations, the personnel consisted of a health officer only; in 171 counties, 1 health officer and 1 nurse; in 35 counties, 1 health officer and 2 nurses; in 124 counties, 1 health

officer, 1 nurse, and 1 inspector; in 33 counties, 1 health officer, 2 nurses, and 1 inspector. A previous study¹ revealed the annual expenditures of the health departments in a representative group of counties to be \$12,060 per annum, or 37.8 cents per capita. As a rule, counties with larger organizations and expenditures than those reported above were either suburban in character or contained large cities in which the county health department was responsible for the health service. The budgets of rural county health organizations tend to remain on a constant low level. With few exceptions, notable increases are peculiar to the wealthier counties and especially those with a large percentage of urban population.

There now remain approximately 2,500 county or comparable districts in which the local government discharges its responsibility for public health through a part-time county physician or through a lay health officer, working under a township or borough board of health. Perhaps a county or community nurse completes the local organization. Most all state health departments make some attempt to supplement the local organization in such services as vital statistics, laboratory diagnosis, and sanitary engineering. It is also the custom of state health departments to employ a limited number of physicians and nurses who operate on an itinerant basis and attempt to give some measure of assistance in areas without organized local health service. The nature of this supplementary service varies, but more usually it is in relation to the control of local outbreaks of communicable disease.

When the public health movement is viewed over a number of years and for the country as a whole, there is observed an unmistakable trend toward the organization of local health service on the

basis of the county or some comparable unit of population. At times such as the present, there have been recessions of local or national significance. It will usually be found that the losses are sustained in counties of limited resources whose health departments were supported to a great extent by extra-county aid. The most important recent gains have been made in the populous, but more particularly the suburban counties, where consolidations are made in the interest of economy.

Another significant change which also augurs well for the future is the fact that practically all states now make some provision in their administrative structure and budget for the development and stabilization of local health service. The states' influence may be exerted in one or more of several ways; such as, passage of rules and regulations to be observed by local health departments, enumeration of duties to be performed, specification of qualifications for local appointees, or through professional consultation in the several branches of the local service. The system of state subsidy, which is an integral part of most state-wide programs of local health organization, has proved to be a useful device in improving the character of service and in stabilizing the organization.

The amount of local autonomy which obtains varies with the individual states. In some states the local health departments are practically independent units. This is particularly true in those states where the central department is not well organized or where all or a very large part of the funds for the local department are derived from sources within the county. The relationship is quite the reverse in other states, especially where a large part of the funds are derived from state appropriation. Under those circumstances, it is the custom for the state health department to certify applicants for local

appointment, to prescribe the program in considerable detail, and to exercise intimate supervision over the local department in other ways. The trend is toward a larger measure of state control of county health service. One state has already adopted a plan under which all local health service is financed and directed by the state health department, the counties being used only as administrative areas; other states are considering similar legislation. In those states where a central plan of financial support and administrative control is adopted, it is entirely possible that the public health map of the state may be redrafted without regard to county lines, perhaps on the basis of metropolitan districts or natural trade areas.

TREND IN PROGRAM

In some respects, the trend in program quite closely follows the pattern of health organization. The part-time lay health officer seldom does more than quarantine for communicable diseases and investigate conditions in the physical environment which give rise to nuisances. If the health officer is a physician serving on part-time basis, medical care of inmates of the county home and of county prisoners may be added to the duties mentioned above. Even in those communities where no attempt is made to supplement such a rudimentary program, the citizens have not remained beyond the influence of the public health movement. Information on health comes to them by means of the printed page, the radio, and by association with others; the food supply is of better quality than formerly, due to the vigilance of national and state authorities; and they are protected from potential epidemics which are checked at distant sources.

While there is often a decided lag between scientific advances and the incorporation of such measures in the

program of a given local official health agency, the more progressive citizens in the community frequently sponsor the work under other auspices. It is not uncommon to find excellent programs of school hygiene, public health nursing, or other special activities in areas where the local official health agency is very weak. Under those conditions, there is no central directing head and special services are apt to be developed out of proportion to other and perhaps more basic health services.

Where health work is administered by some central agency as a county health department, a better balance of program obtains. An attempt is then made to include the commonly accepted services of health departments, such as those enumerated in the *Appraisal Form for Rural Health Work*. However, by reference to previous statements in this paper concerning prevailing county health organizations and budgets for their support, it will be observed that the average county health department is not equipped to do more than touch the outstanding public health problems in a superficial way. The basic services seldom approach accepted standards of adequacy if the budget is much less than a dollar per capita.

The content of the program of county health departments is influenced some by locality. In the South, a large part of the efforts of the health department is directed against intestinal disorders. In the North, acute communicable diseases, tuberculosis, and various aspects of health supervision receive correspondingly more attention.

There has been no reshaping of program such as has occurred in the larger cities through the elimination of garbage collection and similar services relating to cleanliness. Most county health departments have been organized since health departments were relieved of these responsibilities. Furthermore, these are not problems of rural areas

and not a very serious concern of most villages and small municipalities. In some counties where the health department developed around the county physician, medical care of the indigent is part of the program. Prevailing opinion favors the separation of medical care from the health department, although there is a growing recognition of the unity of preventive and curative services. There is considerable agitation for a transfer of established health department functions to practising physicians. This movement, together with curtailment in budget, has brought about a lessening of the actual service content of the program and now greater reliance is being placed on group and community services. It is difficult to estimate the amount of health service actually being taken over by the practising physician, except under artificial conditions. It seems safe, for the present at least, to make the general statement that the type of public health organization which a community maintains determines the content of the program and the character of the service.

TREND IN THOUGHT

In spite of the many forms of health organization which may still be found in the United States, opinion is becoming crystallized on the principles which should govern the administrative structure. These principles may be expressed briefly as follows:

1. Health service should be localized so that the needs of the people may be understood and that the community resources may be used to best advantage. An administrative district of the state government or a suitable local political unit may be utilized for this purpose.

2. The population of such an area should be of sufficient size to make possible efficient administration and an equitable distribution of costs.

3. The basic health services should

be performed by the official health agency since in this way only can they be given the necessary legal backing and stable basis of financial support.

4. All technical positions should be filled by persons meeting definite professional requirements. The health officer and bureau chiefs should present evidence of successful experience in administrative positions in addition to basic professional education.

5. In those states where public health service is a responsibility of local political subdivisions, the state health department should assume such responsibility as may be consistent with local laws and traditions of government for insuring at least a minimum standard of service throughout the state.

These principles, of course, have not as yet found universal application.

Within recent years there has been a remarkable convergence of opinion regarding the services which should be available in any community whether it be urban or rural. These views were first expressed in the Appraisal Forms developed by the Committee on Administrative Practice of this Association. Subsequent revisions of these forms reflect the further evolution of the earlier concepts.

DISSENTING OPINIONS

Perhaps I have given the impression that all public health workers are of one mind and that the product of our labor meets with universal approbation. I have been attempting to depict only predominating movements. There are also well defined movements which go contrary to the main trend. It would be most unjust to many sound and original thinkers if I should fail to give expression to the views of the dissenters within our ranks and to the criticisms of outsiders. Many of these variants deserve careful study, but in this paper it is possible to express only opposing views on a few fundamental issues.

Broadly speaking, the services discharged by organized society for the conservation of health fall into three classes: sanitation, health supervision, and care of the sick. Health departments as a rule have not accepted responsibility for organized care of the sick, except certain communicable diseases. Gradually departments are lessening the amount of personal service in relation to sanitation and health supervision, and instead are relying more and more on education and regulation. A number of county health officers fear that if this course is pursued, it will lead to a rather sterile type of program which will not be sufficiently broad in its appeal to insure permanent support of the health department from public funds. Furthermore, the necessary auxiliary facilities are not available in many counties to complete the service to the individual if the health department confines itself only to making recommendations. It is entirely possible, as some think, that county health departments would be more certain of local support if programs were designed with greater regard for those desires which spontaneously arise in the minds of the people.

In the general field of public administration, there is a pronounced tendency toward making all public services accountable to elected officials either directly or through division heads appointed by the elected officials. Under this scheme, boards are being abolished or if retained, their rôle becomes purely advisory. While this is contrary to our old theories that health must be isolated from general government, it must be admitted that the plan is working successfully in some places, especially where professional standards and security of tenure are insured through an established personnel policy applicable to the government as a whole.

Another tendency in public adminis-

tration is that of grouping related services into a limited number of primary units of government. Many students of the subject see at least two attributes common to sanitation, health supervision and care of the sick: (1) the services are designed for the conservation of health, and (2) persons are prepared for performing these services through training in the biological sciences. They feel that the community would be served more effectively and economically if these related services were combined under unified direction. Opposing views are held by those who believe that the health department should be only a planning and coördinating agency and that others should perform the actual services which the health department recommends.

During the past quarter of a century, in particular, there has been a remarkable reduction in the so-called preventable diseases and an increase in the span of life. The present generation seems to enjoy a higher level of health than did its forebears. These favorable trends no doubt have resulted from a variety of causes, many of which we fail even to comprehend. Public health workers are sometimes accused of being prone to take exclusive credit for these favorable trends. I do not consider this criticism just; on the contrary, if we have erred, it is on the side of modesty in presenting our claims. Nevertheless, these charges should not be brushed aside too lightly since it is not always possible to relate many of our alleged accomplishments to specific preventive measures. In this connection, it is gratifying to record an awakening interest in the subject of health administration. Methods of scientific research are now being applied to various aspects of this difficult art. Until recently we were forced to rely on the experience of individual health officers. The Committee on Administrative Practice of

this Association has attempted to pool these experiences and, through the use of group judgment, to establish standards of practice. It is necessary now to go a step farther and determine in a more exact way the effectiveness and economy of each procedure which enters into the public health program and, where necessary, to devise methods better suited to the needs and resources of the people.

SUMMARY

The desirability of localizing public health service is recognized, but the per capita cost becomes excessive unless it can be distributed over a population unit of considerable size. Most counties have sufficient population and wealth to insure a stable basis of financial support at reasonable cost to the individual. The county, because of being a unit of government, can also give the necessary legal authority to the health officer.

The services comprising a modern public health program cannot be discharged satisfactorily by a part-time physician or lay health officer working alone. An unbalanced and expensive type of program frequently obtains where supplementary services are performed under separate auspices. More and more counties or comparable districts are consolidating all public health services within the area into a single

department under the direction of a full-time health officer especially trained in public health procedures.

Prevailing budgets are below 50 cents per capita, but experience has demonstrated the need of one dollar or more per capita.

Up to the present time, health departments have been concerned primarily with the prevention of disease. Education and regulation are the principal instruments used in the approach. It is now being recognized that preventive and curative measures are closely related and that each scientific advance necessitates a larger amount of personal service in administrative practice. Health departments as a rule do not favor entering curative fields or increasing the personal service content of existing programs. On the other hand, a number of persons concerned with public administration as a whole take the view that the community might profit if the health department were given administrative and budgetary responsibility for those governmental services which are designed to promote or restore health since they are equipped to do so because of training and community contact.

Mirror Manufacturing

AFTER briefly discussing the history and foreign experience with the manufacturing of mirrors, the extent and scope of the industry in the United States and Canada are given, followed by an analysis of the conditions in two typical plants. The different processes

of manufacture are briefly discussed as well as the potential health hazards, and the usual classification and index of jobs, which characterize this series of reports. —Retail Credit Company, Atlanta, Georgia, *Industry Report*, 9, 5:45-52 (May), 1934.

The Use of Laymen in Official Public Health Nursing Programs*

STATE

MRS. ARCH TRAWICK

Associate in Health Education, State Department of Health, Nashville, Tenn.

THE National Organization for Public Health Nursing compiled a census of Public Health Nursing in the United States for 1931, which was published in 1932. I have not succeeded in securing any statistics of more recent date, though I am convinced that these are no longer applicable in many states, because of the reduction in public health budgets and staffs.

The report stated that—"State practices are so variable that it is difficult to discuss any general principles or programs in regard to the status, administration and functioning of public health nursing. Some state departments carry on local health work, and other states maintain an advisory or consultant nursing service. Public health nursing service is an activity of the state health department in 42 states; there are 8 states which have a separate bureau of public health nursing; 12 states in which public health nursing is combined with another activity to form a separate bureau; and 22 states where public health nursing is an activity carried by one of the various divisions of the state health department."

Tennessee belongs in the last named

group of 22 states—and the public health nursing activity is listed under "Central Administration" as a service to county and other local health work. It is really a decentralized service, with one state director directly concerned with supervision in an administrative capacity. It is not, however, an administration of the local services. It is essentially a technical supervisory service. The other state public health nurses serve full-time in the field. The state staff, including the nurses in the tuberculosis control program, has been cut from 16, when the census was taken, to 5. In addition, there are 72 nurses on the staff of 37 full-time county health units and districts, serving more than 40 out of 95 counties, and about 52 per cent of the state's rural population. The nursing staffs of the cities are not included in these figures, nor in this discussion. The public health nursing service, with a few exceptions such as industrial insurance, school, tuberculosis, and Red Cross nursing, is an integral part of the city, county, and state programs of public health.

It is difficult to say that lay groups cooperate with the state public health nursing work, as differentiated from other services of the public health program. In cooperating with the nursing activity, they may be working in the maternity and infancy program, with preschool or school health clinics, in

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

the tuberculosis control program, or improving the vital statistics service.

In the southern states, much of the social order is still rural and agricultural and the organization is simple rather than of the complex type found in more highly industrialized communities. We have fewer or smaller problems of industrialism and immigration. But if we have a less complex civilization, we have serious and stubborn conditions with which to struggle. In most of the southern states we have too many, too small and too poor counties; a dual system of education; a high rate of illiteracy; high tax rates, producing small incomes; isolated, sparsely settled, often inaccessible communities; fewer physicians and inadequate hospital facilities.

We have, in Tennessee, rural counties where the only organized groups are the churches and the schools. We have counties with fewer than 5,000 people, where it is impossible to support adequate school systems and public health service.

Necessarily many statements made in this paper have little bearing on conditions in such states as New York, New Jersey, Pennsylvania, Illinois, Ohio, or California, but, after all, turn about is fair play. After a long apprenticeship spent at national conferences, congresses, councils and conventions, during which I suffered in silence while 95 per cent of the time was given to a discussion of the problems of New York, Chicago, Philadelphia, and other large cities, I can sympathize with you as you are forced to listen to this voice from the wilderness—from the real hinterland.

Because our programs of public welfare and social work are of more recent development, we have collected few barnacles on our organization, beyond those due to causes already mentioned. If we have no less violent opposition to progressive measures, it comes from a

homogeneous population. We have the opposition of plain ignorance, prejudice, and superstition. But it is not colored by the additional complications of heterogeneity as evidenced by differences in language, religion, modes, and customs. On the same economic levels, you will find the whites and negroes amazingly alike in habits and attitudes. We may not speak the speech trippingly, but even a social worker from Boston can make a lucky guess at a Tennessee mountaineer's meaning. And today we have an almost universal language of unemployment, of poverty, of human need.

It will be generations before our rural states can maintain adequate nursing service without outside help from the federal government.

In 1931, the total number of public health nurses in the United States was 15,865—an average of 1 nurse to almost 8,000 people, but very unequally distributed. The National Organization for Public Health Nursing tells us that if we desire adequate service we should have 1 nurse to 2,000 people. On that basis, no state has yet reached a satisfactory standard. In 1931, Connecticut had the best record—an average of 1 nurse to 3,000. Massachusetts had 1 to 3,675, New Jersey, 1 to 4,000, New York, 1 to 4,700, Pennsylvania, 1 to 6,424. Ohio's figures were 1 to 6,082, Michigan, 1 to 5,400, Illinois, 1 to 8,000, Iowa, 1 to 12,900, Nebraska and Kansas, 1 to 14,000—North and South Dakota, 1 to 27,000 people. California's record is the best in the Far West, 1 to 6,500. Coming south, we find in Maryland 1 nurse to 6,150; Virginia, 1 to 10,400; Tennessee, 1 to 12,450; with an increase in Kentucky, Florida, North Carolina, Georgia, South Carolina, Alabama, Arkansas, Oklahoma, until we reach the climax in Mississippi, where we find 1 public health nurse to 51,550 people.

To the scarcity of public health

nurses we must add other factors already discussed: a widely scattered, often inaccessible rural population. Many times the neediest groups live far from any beaten path, in coves or valleys or on the steep mountain sides. We may find in these communities a high maternal and infant mortality rate, much tuberculosis, trachoma, pellagra, typhoid fever, with malaria down in the lowlands, and other diseases due to ignorance, poverty, malnutrition and lack of sanitation.

The Tennessee Department of Public Health is under no delusions as to the size and importance of its task. The Commissioner, Dr. E. L. Bishop, and his staff have moved forward as rapidly as it has been possible to develop informed local support and cooperation. A systematic effort has been made to carry a balanced program without undue emphasis on any one phase of public health service. The pattern followed is that of the full-time county health unit, with a minimum personnel of 3 trained workers and a clerk. Cooperation of counties is voluntary (there is no mandatory legislation compelling the establishment of whole-time health services). The unit of government is the county, governed by the county court of magistrates.

From the beginning of the present public health program, in 1924, there has been a steady campaign to interest the voluntary agencies, and to secure their support and cooperation in stabilizing and extending the services of the department. In 1926, the State Federation of Women's Clubs established a policy of active cooperation in the campaign to place Tennessee in the birth registration area. In many places, club women made a thorough house-to-house canvass. In 1932, the State Legion Auxiliary and State Congress of Parents and Teachers gave valuable help in rechecking the census figures on birth registrations.

These incidents do not bear directly on public health nursing, but indicate the use of the voluntary agency in the interpretation of health facts and in the exchange of information. The voluntary organization serves as a voice for the people most concerned, and helps in the integration of public and private agencies. It supplements the service of the official agency and makes possible more effective, better coordinated machinery.

Several years ago, one of my friends, a distinguished public health nurse, went to one of the large eastern industrial centers, to organize a public health nursing council. In that city, there were more than 70 agencies with independent programs, employing public health nurses. Situations such as this do not obtain with us because of two causes: lack of funds, and lack of old established programs of social work. Our main difficulty is often the reverse of such conditions. There may be no organization to provide a channel of education and interpretation.

You have heard from previous speakers that public health nurses may serve under local boards of health and boards of education, and under official agencies, semi-official or private groups—tuberculosis associations, Red Cross, insurance companies, industrial or commercial concerns, or social settlements and other welfare agencies. In many places, these agencies have a central council to prevent overlapping and duplication. In the counties, we may find more independence of action, more duplication and wasted effort, less unification of program and objectives. We see instances where national boards or agencies, in a desperate search for a program to provide a basis for financial appeal, insist on independent action. This is done in order that it may receive greater publicity, keep its prestige, and maintain a large organization for the raising of money. The funds secured

are often spent on unnecessary or insignificant causes—when through co-operation with the official and other voluntary agencies they might be of great constructive value.

We find fewer conflicts in the field of state organizations because many of the agencies, with nursing service, have only local connections. Several state-wide lay organizations have definite policies of coöperation with the state and local departments of public health. The state organization of the D. A. R. undertook the partial support of the first public health nurse in a mountain county, and continued this project through the State Department of Public Health until the county was ready to take over its part of the support of the entire health unit. The State Federation of Women's Clubs has contributed for several years in the same manner to the salary of a public health nurse who works in a district composed of two counties. The Federation is just entering upon a second similar project in a very backward county. The counties are chosen by the State Department and the coöperating agency because of their health needs, and their financial condition. The nurses are selected by the State Department of Public Health. Reports are sent quarterly to the co-operating agency, and are made by the nurse in person at annual conventions. In addition, the State Federation of Women's Clubs, the State Congress of Parents and Teachers, the State Federation of Business and Professional Women's Clubs, the State Legion Auxiliary, and the W.C.T.U. have, among their definite objectives, co-operation with the State Health Department in securing full-time public health service for all the people of the state.

Some of these state organizations have printed programs on the organization, policies and services of the state and local health departments.

Local, county, and district groups coöperate in various health projects, such as Summer Round Ups, Blue Ribbon Program, Well Baby Clinics, and in the organization of local health committees and county health councils. All of this work is direct coöperation with the public health nurses. Local health committees help with clinics, with supplies, transportation, publicity, education, and financial support. State organizations coöperate in the state legislative program. Most effective work has been done in the program of legislation for the State Department of Public Health by the above mentioned groups.

One of the most successful efforts in state-wide coöperation was the Tennessee Conference on Child Health and Protection, held in November, 1932. The findings of that conference have gone back to the organized county groups to be translated into action, thus bringing into a community of thought the problems of child health, education, training and welfare, with the economic background necessary for their understanding and solution. The worth of county-wide health councils has been clearly demonstrated in Tennessee. They have proved the value of continuous volunteer service as an integral part of a program of public health. They serve as case finding media, they help to overcome the diffusion in rural health work, and have a long record of achievement in the correction of defects, in securing immunization, in the field of investigation, and in educating the public to the necessity of financial support for a growing program. Local health committees are a necessity in districts where the nurse serves a large county-wide unit of population. State organizations in Tennessee urge their local groups to participate in the ever-widening field of community coöperation.

I have a letter from one of the chair-

gation conducted in 1926 when precipitation tests made by Dr. Kahn were included was of particular significance since a comparative evaluation of the methods widely used in North America and those represented in the conferences held under the auspices of the League of Nations at Copenhagen and Montevideo was thus made possible.

Finally, the progress reports include the comparative series of tests made in laboratories operating in the State of New York under supervision and approval. The results provide a convincing demonstration of the importance of the adoption of methods which, although they may differ somewhat in detail, are sound in principle and so carefully adjusted as to provide a guard against reactions with non-syphilitic sera that may occur in oversensitive tests. In the comparative tests of this series, reactions were seldom obtained by any of the methods included in the study with specimens from patients free from history or evidence of syphilis. In two laboratories where identical methods were used, differences of negligible degree only occurred. Thus, for purposes of a standard method all the data available indicate the desirability of specifying the elements of technic essential for accuracy and omitting details which have not been proved to be necessary. The proposed method was submitted to serologists in Canada and the United States for their opinions of its value and received most favorable consideration.

GENERAL REQUIREMENTS

I. *Qualifications of personnel*

An individual who is familiar with the clinical manifestations of syphilis, and who has had thorough training in serology, pathology, and bacteriology, should be directly in charge of the work. As an alternative, a consultant, who is familiar with the clinical mani-

festations of syphilis, should be available to evaluate the findings.

II. *Minimum number of examinations*

The test should, in so far as possible, be performed in laboratories examining relatively large numbers of specimens, not only for purposes of economy, but for the greater reliability of results. It is desirable that the minimum number of examinations should be 50 per week, and that the test should be made at least twice weekly.

III. *Provision of standardized reagents*

The provision of antigens and amboceptor should be undertaken by central laboratories having adequate facilities for their standardization. Such laboratories should also arrange to furnish, for purposes of control, syphilitic sera which give reactions of known strength.

IV. *Nature and condition of specimen*

A. The specimen should consist of blood or spinal fluid, as free as practicable from contamination. Hemolyzed specimens of blood or spinal fluid showing evidence of bacterial growth should not be considered satisfactory for examination.

B. Each specimen should be accompanied by sufficient history for purposes of identification and for the evaluation of the results of the test.

V. *Identification of specimens, records, and reports of examinations*

A. Each specimen should be given a serial number as soon as opened in the laboratory.

B. Complete records of all examinations should be filed permanently.

C. A signed, written or typed report of the result of the examination should always be sent to the physician.

VI. *Equipment*

A. Glassware:

1. All glassware should be chemically clean.

2. Only graduated pipettes (or automatic pipettes regulated to deliver measured quantities) should be used for measurement of the various constituents of the test other than salt solution.

3. A separate pipette should be used for each specimen and for each reagent.

4. The tubes for the test should be of such size that the reagents can be readily mixed.

B. Water bath:

The baths should be so constructed as to maintain in every part the temperature required for inactivation or for incubation.

C. Refrigerator:

The refrigerator should be such as to maintain in every part used the temperature required for fixation.

TECHNICAL REQUIREMENTS

I. *Preparation and standardization of constituents*

The diluent for all reagents should be a salt solution containing chemically pure components isotonic for red blood cells.

A. Patient's serum and spinal fluid:

1. Preparation—

Serum should be freed from blood cells and inactivated by heating in a water bath at 55° C. (The period of inactivation should be constant and should not be more than $\frac{1}{2}$ hour nor less than 15 minutes.) The natural antisheep amboceptor should be absorbed, if present in sufficient quantity to affect the sensitivity of the test. Spinal fluid should be freed from cells or sediment, and if it contains blood, should be inactivated in the same manner as blood serum.

2. Quantities to be tested—

The largest quantity of serum tested should be at least the equivalent of that used by Wassermann, 0.2 c.c. (the total volume of the test being 5 c.c.),

and preferably 2 or 3 times this amount; the largest quantity of spinal fluid tested should be from 5 to 10 times the volume of serum employed. At least one-half the largest amount of serum or spinal fluid should also be tested to detect so-called prezone reactions.

B. Antigen:

1. Number and kinds of antigens—

Lipoidal extracts of normal heart muscle, preferably beef heart, furnish a satisfactory base. At least one of the antigens used should be reinforced with cholesterol. Tests with two antigens or another generally accepted serologic test (precipitation or flocculation) for syphilis should be performed for purposes of confirmation.

2. Standardization—

Antigen should be accurately titrated for lytic, anticomplementary, and antigenic properties. Only antigens with a wide range between the dilution in which they react with syphilitic sera and that in which they are anticomplementary, in which they give fixation with specimens from normal persons, or in which they are hemolytic, should be used.

C. Complement:

1. Preparation—

The serum for complement should be obtained from healthy guinea pigs, preferably males. The individual sera should be tested for hemolytic activity, both with and without addition of amboceptor, for fixability in the presence of syphilitic sera and antigen, and for failure to react appreciably with antigen alone. Only those found to be satisfactory should be included in the pool of sera from three or more guinea pigs. The complement serum, after withdrawal from the clot, should be kept undiluted at a temperature of from 0 to 6° C. until used, and should not be more than 48 hours old when the hemolytic system is added to the tests.

2. Titration—

The hemolytic value of the complement should be determined each day not more than a few hours before the tests are made. The same red blood cells and hemolytic amboceptor should be used for both. Complement varying widely from the average in quality should be discarded. The amount of complement used in the test should represent a slight excess over the minimum required for complete hemolysis in the presence of non-syphilitic serum and antigen as determined by repeated quantitative experiments with the antigens and method of fixation employed.

D. Suspension of sheep's red blood cells*:

The blood should be collected aseptically. The blood cells should be freed from serum by at least three "washings," not less than 10 volumes of salt solution being used to each volume of cells, and after the final washing, the supernatant fluid should show no appreciable hemolysis. The suspension should contain a definite proportion of packed cells by volume and should be prepared in such a way as to be of practically constant density.

E. Antisheep hemolytic amboceptor:

1. Preparation—

The amboceptor—antisheep hemolytic serum—should be produced by immunization of an animal and should be markedly hemolytic and practically free from agglutinative properties in the dilutions used. Fluid serum rather than serum dried on paper should be used. This should be inactivated and stored in sterile ampules or preserved by the addition of an equal volume of T. P. glycerol.

2. Titration—

The hemolytic value of the ambo-

ceptor in terms of the standard amount of red blood cells should be determined accurately by titration with different specimens of complement. The amboceptor should have no demonstrable agglutinating effect in the dilution used. The amboceptor should be added in the same manner to complement-fixation tests and to titrations of complement or antigen, either combined with the red blood cells or separately. The period of incubation, also, should be the same for titrations of complement and amboceptor.

II. *Method of conducting the complement-fixation test*

A. Combining the constituents:

After the serum or spinal fluid, antigen, and complement have been combined, the volume in all tubes should be equalized by the addition of a sufficient amount of salt solution and the racks shaken to mix their contents thoroughly.

B. Temperature and period of fixation:

A prolonged period of fixation at a low temperature is essential. At least 4 hours at from 0 to 6° C. are required and an additional exposure of from 10 to 15 minutes in the water bath at 37° C. is desirable. Otherwise, provision should be made for an additional test with incubation at 37° C. for from ½ to 1 hour in case the history indicates the possibility of recently acquired syphilis.

C. Period of secondary incubation:

The period of secondary incubation, i.e., the incubation at 37° C. following the addition of the hemolytic system, should approximate that used for the titrations of complement and amboceptor.

III. *Controls*

The following controls should always be included:

A. A test of each blood serum and

*An antisheep hemolytic system is specified because normal sheep blood can usually be obtained easily in large quantities and antisheep hemolytic serum of high titer is easily produced.

each spinal fluid without antigen as a control upon anticomplementary properties.

B. Tests of each antigen without serum in the same and in at least 4 times the amount used in the tests.

C. A test of each antigen with a syphilitic serum previously found to give complete fixation and also with one found to give only partial fixation.

IV. *Reading and recording of results*

A. Inspection of controls:

At the time that the readings are made, the anticomplementary controls of each serum and spinal fluid and the controls of the antigens used in the tests should be completely hemolyzed. The control tests with syphilitic sera should show no hemolysis and partial hemolysis respectively.

B. Reading and recording reactions:

The degree of complement-fixation should be estimated from the proportion of unhemolyzed blood cells in each tube, preferably by comparison with standards containing known proportions of hemolyzed and unhemolyzed cells. The result of the test should be recorded without reference to the clinical history. When the reactions with the different antigens disagree, or the results of the complement-fixation test do not correspond with those of the other serologic

test for syphilis used, or when there is any evidence of technical inaccuracy, the findings should be verified by repetition of the tests. Further confirmation may be considered necessary when reactions occur that are unexpected in view of the history submitted. The results of the complement-fixation test for syphilis should always be evaluated with reference to the clinical manifestations.

Place Variation in the Death Rates from Puerperal Septicemia*

Large Cities of the United States, 1922-1929

G. E. HARMON, M.D., F.A.P.H.A.

*Department of Hygiene and Bacteriology, School of Medicine, Western Reserve
University, Cleveland, Ohio*

IT is well known that during recent years the death rates from puerperal septicemia have shown no tendency to decline. The conclusion might be drawn from this fact that either no measures of control have been employed or that those which have been used are of no value. If, however, there is a possibility of reducing the rates, then, in case the first explanation holds, an incentive is supplied for attempting to institute proper measures and for changing to better ones if the second explanation holds. If, on the other hand, reduction of the rates is impossible under present conditions, then an excuse is at hand for the recorded failure.

What, then, is the possibility of reducing the death rates from puerperal septicemia? Some statistical information was sought upon this question by studying the variation from place to place exhibited by the death rates from puerperal septicemia for large cities with the idea in mind that if the observed variation exceeded that which might be ascribed to chance, then reduction in the rates under present conditions would seem to be a possibility.

There are 55 cities in the United States, each of which had a population of 100,000 or more in 1920, and each of which was continuously in both the birth and death registration areas from 1922 to 1929. For each of these cities for every year of the period the total births (the sum of the live births and the stillbirths) were obtained from "Birth, Stillbirth, and Infant Mortality Statistics,"¹ and the deaths due to puerperal septicemia from "Mortality Statistics."² For each year of the period death rates from puerperal septicemia per 1,000 total births were calculated for each city. There were thus 8 yearly series of rates.

In studying the place variation exhibited by these series of rates it was apparent that methods must be used which would make due allowance for differences in size of city. This was accomplished by calculating the weighted mean and the weighted standard deviation for each series of rates. In obtaining these constants each city was weighted according to its size measured in total births. A weighted theoretical standard deviation was calculated for each series upon the supposition that each series was distributed according to the binomial law. The Lexian ratio for each series was also obtained by merely dividing the

TABLE I

PUERPERAL SEPTICEMIA: SUMMARIZED DATA AND STATISTICAL CONSTANTS FOR
55 LARGE CITIES OF THE UNITED STATES, 1922-1929

Year	Sum of Total Births	Sum of Deaths from Puerperal Septicemia	Weighted Mean Rate per 1,000 Total Births	Weighted Standard Deviation	Weighted Theoretical Standard Deviation	Lexian Ratio
1	2	3	4	5	6	7
1922	582,817	1,519	2.61	0.800	0.496	1.61
1923	595,547	1,654	2.78	0.944	0.506	1.87
1924	612,571	1,656	2.70	0.894	0.492	1.82
1925	599,608	1,644	2.74	0.872	0.501	1.74
1926	590,180	1,553	2.63	0.947	0.494	1.92
1927	593,741	1,620	2.73	0.900	0.522	1.72
1928	578,930	1,550	2.68	0.836	0.504	1.66
1929	567,341	1,495	2.64	0.838	0.505	1.66
Total	4,720,735	12,691				

actual weighted standard deviation by the weighted theoretical standard deviation.

The results obtained are brought together in Table I. It will be seen that column 4 justifies the statement made at the beginning that the rates from puerperal septicemia have remained practically stationary during recent

years. It is also evident from columns 5 and 7 that the amount of variation in the rates, whether judged by the weighted standard deviation or the Lexian ratio, has remained about the same throughout the period. Furthermore, the Lexian ratios are always greater than one, indicating that for each year the amount of variation actually exhibited by the rates exceeds that which might be ascribed to chance.

A similar table for comparative purposes was prepared for each of the following causes of death: diarrhea and enteritis under 1 year of age, congenital defects under 1 year of age, and early infancy. The more important results are presented in Figures I and II. The weighted mean rates (Figure I) for early infancy show a slight decline, and those for diarrhea and enteritis a marked decline. The rates for the other two causes have remained stationary. The Lexian ratios (Figure II) throughout the period are larger for

FIG. 1. WEIGHTED MEAN DEATH RATES FOR CERTAIN SPECIFIED CAUSES. 55 LARGE CITIES OF THE UNITED STATES. 1922-1929.

diarrhea and enteritis than for either of the other diseases, puerperal septicemia having the smallest Lexian ratios.

FIG. 11. LEXIAN RATIOS FOR CERTAIN SPECIFIED CAUSES, 440 LARGE CITIES OF THE UNITED STATES, 1922-1929.

Furthermore, the Lexian ratios are greater than one. It is of interest to note that as the rates from diarrhea and enteritis have declined the corresponding Lexian ratios have declined also, evidence that the greater the control of a disease the less will be the place variation exhibited by its rates. If the amount of place variation exhibited by rates is at all indicative of the possibility of their control, one is forced to the conclusion from a study of Figure 11 that there is much less possibility of further controlling puerperal septicemia than of controlling diarrhea and enteritis. In a rough way, it would seem that puerperal septicemia, congenital defects and early infancy constitute a group of diseases with about equal possibilities of further control.

The data for the cities were next analyzed in the following manner: the 3 series were combined into one, thus a description of the experience of 440 cities for an interval of 1 year was obtained. This somewhat artificial point of view is justified by the fact that judged by the constancy of the observed rates and the smallness of their variation, the factors affecting the incidence of puerperal septicemia must have re-

mained approximately the same from year to year.

If, now, for such a series of cities, p equals the chance of dying, $(1-p)$ or q equals the chance of not dying, s equals the base upon which rates for the cities are calculated, and m equals the mean size of city, then, as has been shown by Fisher,³ the weighted theoretical standard deviation is equal to

$$\sqrt{\frac{s^2 p q}{m}}$$

If s be taken equal to m , then the formula becomes $\sqrt{m p q}$, the standard deviation of the binomial $(p + q)^m$.

The mean size of city was found to be $\frac{4,720,735}{440}$, or 10,729 total births. A death rate for each city was calculated

TABLE II

Standard Deviation	13.130	5.655
Lexian Ratio	2.32	

using this figure as a base. The distribution of these rates appears in Table II alongside the distribution which would have been expected if chance alone were the controlling factor in a universe in which the chance of dying is 0.00299. This latter distribution represents the expansion of the binomial $(q + p)^m$ in which $p = \frac{32.1}{10,729}$, or 0.00299; $q = 1 - 0.00299$, or 0.99701, and $m = 10,729$. Since for the binomial $(0.99701 + 0.00299)^{10,729}$, $B_1 = 0.031$ and $B_2 = 3.031$, its expansion was approximated by using the normal curve.

The chi-square test was carried out on these distributions and the value obtained (5,208) is so large that there is practically no likelihood that the actual distribution could be a random sample from a population of cities in which the probability of dying from puerperal septicemia is 0.00299. In other words, the actual distribution is dependent upon other factors than chance.

A comparison of the two distributions

reveals the fact that more cities have low rates and more cities have high rates than would be expected on the basis of chance alone. This situation is favorable for a further reduction in the mean rate for all the cities because the hope would seem to be justified that the conditions favorable to low rates, experienced by some cities, might be determined and be duplicated in the cities with high rates.

These two methods of statistical analysis of the data available for large cities of the United States justify the hope that the reduction of the present high death rates from puerperal septicemia is a possibility.

NOTE: The author wishes to acknowledge his indebtedness to Miss Huldah Bancroft for assistance in making arithmetical calculations and in drawing up the tables and graphs.

Purification of Vaccinia Virus*

MORRIS SCHAEFFER AND HELEN NALIBOW

*Department of Bacteriology, University and Bellevue Hospital Medical College,
New York, N. Y.*

THE success attained by chemists in preparing purified or concentrated extracts of tissue containing enzymes and other biological products has stimulated similar attempts upon the tissues of animals infected with filterable viruses.^{1, 2, 3} The virus of vaccinia has received considerable attention in this respect, due in part perhaps to the economy and facility of laboratory manipulations and to the accessibility of applying practically, some of the observations made. Thus, in the last few years, many investigators have reported on adsorption,^{4, 5} purification,^{6, 7, 8} and filtration^{9, 10, 11} experiments with vaccinia virus.

We wish to report a number of observations which after further investigation should lead toward a highly purified and readily filterable vaccinia virus. In order to give a clear understanding of the reasons for our steps it is necessary to describe the actual sequence of our experiments.

An attempt was made to determine the duration of survival of vaccinia virus in milk. The Levaditi neuro-strain, maintained by testicular passage in rabbits, was employed. Two series of flasks were set up as follows:

1. A series containing 75 c.c. of whole defatted pasteurized milk and 25 c.c. of a third generation tissue culture of vaccinia virus in Maitland's medium

2. A series containing 99 c.c. of whole de-

fatted pasteurized milk and 1 c.c. of a 1 per cent emulsion of a glycerinated vaccine testicle

The milk was titrated and tested on the skin of rabbits at intervals and at the end of 183 days the virus in both series still retained its original potency. No tests were made between the 6th and 11th months. By the 11th month the virus had diminished in nearly all of the samples. These samples, however, were found to be highly contaminated with bacteria, so that it is possible that the virus might have survived for a longer period.

The testicle of a rabbit which had reacted weakly was sliced longitudinally, one half stored in 50 per cent glycerine, the other in milk and both kept in the refrigerator. At the end of 4 weeks the glycerinated testicle was entirely devoid of virus while the half preserved in milk still gave an appreciable reaction on rabbit skin in a dilution of 1-5,000. The survival of the virus in milk might possibly be explained on the basis of protective colloidal action, as is indicated by observations which followed.

Shortly after setting up the aforementioned series of flasks containing virus and milk, one of the samples which had been left out of the refrigerator turned sour due to bacterial contamination. Both the precipitated casein and whey were tested for presence of the virus. Nearly all of the virus was adsorbed on the casein, while the whey contained a little of the virus, which, however, filtered through a Berkefeld V

*Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

candle without loss. Fresh samples of virus ground in milk, when precipitated with acetic acid, behaved in a similar manner. It was also possible to adsorb the virus on precipitated, washed, and acidified casein directly from emulsion made in saline solution and release it from the casein, by washing with dilute alkaline solutions.

Employing a purified casein (Harris) as adsorbent it was found that good adsorption takes place at pH 4.9–5.5, and that the virus is released when the pH is shifted above or below 4.6, the iso-electric point of casein. The optimum, however, was found to be between pH 7.6 and 8.5.

Although potent yields of virus can be obtained by this method it is not entirely satisfactory since the resulting solutions contain casein and the virus is completely lost on filtration.

Comparative studies with other adsorbents such as kaolin, silica gel and aluminum hydroxide (Type C, Willstaetter) showed that each of these gels adsorbed well. Elution, however, was difficult, giving poor yields of virus at best. Filtration experiments with the best of these eluates were negative. This difficulty was also encountered by Parker and Muckenfuss¹² who attempted to purify vaccinia virus for complement fixation studies. The combination of alumina gel with casein resulted in an eluate which contained the highest yield of virus which passed through both the Berkefeld and Seitz filters. The following procedure was used:

An amount of a 5 per cent suspension of purified casein in distilled water is added to an equal amount of aluminum hydroxide (standardized to contain approximately 22.5 grams of aluminum oxide per liter). The mixture is adjusted to pH 4.9–5.5 with KH_2PO_4 . To a volume of this mixture is added an equal volume of a 5 per cent emulsion of either fresh or glycerinated vaccine testicle in physiological saline solution. These are kept in contact from 2 to 4 hours, then centrifuged, the precipitate washed with

distilled water, and the volume of liquid replaced with equal volume of basic solution. The pH of the mixture is adjusted to about pH 8.2–8.5. In from 2 to 4 hours the supernatant is removed containing a potent virus which filters consistently through the Seitz without loss in potency and through both the Berkefeld V and N with only slight loss.

The ease with which filtration is accomplished by this method may be comparable to the filtration of the whey of precipitated milk-virus mixture.

In this work we confirmed the observation of previous investigators as to the rapid deterioration of vaccinia virus in saline emulsion. Adsorbed virus, on the other hand, retains its original activity for several days at least.

In attempting to repeat the work of Behrens and Morgan⁸ on purification by iso-electric precipitation, using testicular emulsions instead of brain, we observed that although we began with a highly potent virus it was completely inactivated when pH 6 was reached, upon addition of acetic acid. This is of interest since the virus, in the presence of an adsorbent, is not affected by acetic acid even at pH 3.2. We could confirm neither the results of Yaoi and Kasai⁶ on the filtration of emulsions at alkaline pH having tried filtration at various acid and alkaline pH, nor those of Green and Eagles¹³ who obtained filtrates of emulsions made up in distilled water or by first passing acidified egg white through the filter.

In an effort to determine whether the casein-alumina method could be applied for practical purposes, an emulsion of calf scrapings was adsorbed, eluted, and filtered in the manner described above. The results obtained with calf scrapings are encouraging but not yet quite as good as those with testicular virus.

At this stage of our work, it is difficult to attach particular significance to any of our observations. Further study in this direction may perhaps result in

the accumulation of sufficient data with which valuable information concerning the properties of vaccinia virus can be formulated.

NOTE: The authors wish to thank Charles R. Tyler of the New York City Department of Health Bureau of Laboratories for repeating and confirming the purification and filtration results both with testicular and dermal viruses.

Senate Bill 41

PASSED AT SPECIAL SESSION 1933 AND PUBLISHED DEC. 5, 1933

An Act to control stream pollution and providing for the work authorized in sections 65-171a, 65-171b, and 65-171c of the Revised Statutes Supplement of 1931.

BE IT ENACTED BY THE LEGISLATURE OF THE STATE OF KANSAS:

Section 1. That for the purpose of preventing stream pollution detrimental to public health or to the animal and aquatic life of the state, the state board of health, with the approval of the state forestry, fish and game commission, shall make rules and regulations governing the disposal of domestic and industrial sewage wastes by municipalities, corporations, companies or individuals: PROVIDED, HOWEVER, Such rules and regulations shall not prohibit storage of salt water, oil, or refuse in tanks, pipe lines, or ponds. The State Board of Health shall fix fees to cover the cost of services rendered under said rules and regulations, which fees shall be approved by the attorney-general,

and board of regents before they shall become operative.

Section 2. All investigations and services rendered under the provisions of this act shall be made by the division of sanitation of the state board of health in the University of Kansas, and all fees collected shall be turned in to the State Treasury for the benefit of said division of the University of Kansas.

Section 3. Every company, corporation, or individual that shall fail to comply with the rules and regulations of the State Board of Health authorized by this act, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by a fine of not less than twenty-five dollars and not more than one hundred dollars for each offense. The failure to comply with such requirements in each day in which failure is made, shall be considered to constitute a separate offense.

Section 4. That this act shall take effect and be in force from and after its publication in the official state paper.

The Sanitary Works of Indianapolis*

C. K. CALVERT

Superintendent, Indianapolis Sewage Treatment Plant, Indianapolis, Ind.

SEVERAL years after the Indianapolis Sanitary District was established in 1917 to handle the sewage of the city, the law was amended to include the collection and disposal of ashes and garbage.

Non-inflammable refuse, including ashes, is collected bi-weekly in summer and weekly in winter, and dumped on low ground. Suitable places are available in many localities and the hauls are short. The cost of disposition of 160,000 yards in 1932, including the maintenance of dumps, was at the rate of \$0.707 per cu. yd. Garbage, free from tin cans, broken crockery, paper, etc., is collected semi-weekly in summer, and weekly in winter, from the residence section, and nightly from the hotels and restaurants. It is hauled by trailer train to the garbage disposal plant located on the Sanitation Plant grounds in the southwestern corner of the city. The cost of collection of 30,000 tons in 1932 was at the rate of \$2.505.

At the reduction plant the garbage is cooked at 80 lb. pressure for 2 hours, the grease and liquor drained and the residue dried under vacuum in the cooking tanks, which are steam jacketed. The dried tankage is separated by a current of air into light and heavy portions. The light material, substantially free from glass and metals, is sold as

stock feed with a protein content of about 16 per cent and grease of from 20 to 25 per cent. The heavier portion is percolated to recover the grease and the residue sold as fertilizer base with an ammonia (NH_3) content of about 3.5 per cent. Grease, sold for soap making, is the most valuable product, with fertilizer base second. In so far as the limitation of the physical plant permits, the relationship between fertilizer and feed production is governed by the market. Degreased feeding tankage is finding increased favor under the name of Table Scrap Meal and is more profitable since the grease from it is sold for soap making at a higher price than it commands as feed.

The cost of reducing 28,600 tons of green garbage in 1932 was at the rate of \$3.25 per ton. With interest and depreciation added, the total is \$6.00 per ton. The by-products were—Grease, 66 lb., fertilizer base, 228 lb., and feeding tankage, 23 lb., per ton of green garbage. The price for the materials varies from year to year. In 1929 the return was \$165,000, and in 1932, \$32,000. In the past 5 years, by-products have returned \$3.30, operation has cost \$3.52, and interest and depreciation have been \$2.68 per ton of green garbage.

Sewage, slaughterhouse, and canning wastes had so befouled White River that a survey made in 1904 by Prof. Robert L. Sackett disclosed a black, foul stream which recovered only after many miles of flow. While an Imhoff-sprinkling filter experiment station was operated about 1912, no real progress was made

* Read at a Joint Session of the Conference of State Sanitary Engineers and the Public Health Engineering Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

until suits by riparian owners forced the formation of the Indianapolis Sanitary District by the 1917 legislature. The progress of the war interfered with construction, but in 1921 work on the sewage disposal plant itself was started. The clarification plant was operated in 1924 and the activated sludge plant was put in service May, 1925, and both have operated continuously since.

Indianapolis sewage is strong. The census shows the population to be 375,000 but on the basis of B.O.D. of the sewage it is 673,000. While the city covers some 54 sq. miles, the sewage is comparatively fresh when it arrives at the plant. Industrial waste, affecting the strength of the sewage, comes from a large meat packing industry, starch works, and canning plants. In spite of the size of the city and the volume of its manufacturing, there is a very marked daily and weekly cycle in the volume and concentration of organic matter.¹ Such variation presents problems in connection with the operation of the activated sludge plant. With rather indifferent success, considerable time is spent with producers of industrial wastes in an effort to prevent discharge to the sewers of, (1) solids, (2) inflammable liquids, and, especially, (3) grease and oil of all sorts. An unusual appearance of the sewage or the presence of more than average grease or oil is reported at once, day or night, by the grit chamber attendant, and an inspector endeavors to trace it to its origin, which is usually difficult on account of elapsed time.

The first actual treatment given to the sewage is at the grit chamber which it enters through a fixed bar rack with $1\frac{1}{2}$ " clear openings. Rags, entrails, and general debris are removed and burned in a refuse incinerator. The velocity in the grit chamber is about 1' per second, and the detention 1 minute.

The grit is quite clean and used to fill adjacent low ground. Skimmers, located at the downstream end of the grit chamber, retain, and pumps remove such material as may rise to the surface under the conditions imposed. No special oil removing treatment is given and, with the short detention time, removal is imperfect. In order to remove the greatest possible amount of grease the sewage is skimmed at two subsequent points. The skimmed material is burned on an isolated bank. There are 4 grit chambers located ahead of inverted siphon river crossings. The main chamber is given constant attendance and the 3 smaller ones visited once or twice daily depending on the rainfall.

As the sewage reaches the plant proper, it is skimmed and passed into the clarification unit which is of unique design. Three cylindrical screens, with openings $1/16$ " x 2", rotate partially submerged as the sewage flows through a channel. The flow is controlled so that approximately two-thirds of the sewage passes through the screen and one-third, carrying the solids rejected by the screen, passes out at the bottom of the channel to rapid settlers each 12' deep, 15' wide and 120' long, which provide a detention period of about 20 minutes. Sedimentation is very rapid and clean on account of the concentration of the solids. The combination of fine screens and sedimentation results in the removal of almost 40 per cent of the suspended solids. The solids settling on the bottom of the basins are collected mechanically, and 5 per cent solids sludge pumped to deep earthen digestion pits. The settled and screened portions of the sewage mix in a suction well from which they are pumped as clarified sewage to the activated sludge plant. To this point the flow is by gravity except from one small section of the town from which automatic pumps lift the sewage to the gravity lines.

Just before the clarified sewage reaches the activated sludge plant, the returned sludge is added and mixed. The mixed liquor flows into a distribution channel which feeds all the aerators. Spiral flow, induced by air diffusers placed along one side of the aerator only, was first put into service at Indianapolis, and since that time every plant of any size constructed in the United States has been of this type. The diffusers are placed in depressions formed at the time the floor was poured. They are sealed in place with Portland cement which makes removal of whole plates out of the question. The mixed liquor is held under aeration as it flows through the 4 passes of the aerator, the designed period being from 5 to 5½ hours. In practice, the period has been much longer, due to lack of capacity in the settlers.

The mixed liquor passes through a venturi meter between the aerator and the settlers, which are octagonal at the top, and round at the bottom. The feed enters at the ends of the basins, which are substantially 42' x 78' in plan. The clear liquor is taken off by troughs with V-notch weirs and the sludge is removed continuously from the bottom at the center. The mechanism consists of a central drive shaft with a cross-arm at the bottom which carries a slack chain to drag the bottom and prevent the sludge from sticking. The sludge detention time in the settlers is a matter of minutes.

At the time the plant was constructed, a building was partially equipped for the filtration and dehydration of sludge for fertilizer. It was operated for a 6 month period in 1931, the equipment being sufficient to handle about 20 per cent of the activated sludge produced. This period of operation indicated that the cost of production, working at full capacity, would be about \$15 per ton of dry solids, which is more than can be realized for the product at this time.

Indianapolis sludge requires an excessive amount of chemical conditioner before filtration and its cost offsets, to some extent, the low fuel and labor prices enjoyed.

At present the waste activated and primary sludges are digested in deep earthen pits which have given no odor trouble. The method has been very economical and satisfactory since a considerable area is available for this use. Sludge is not seeded as it is pumped to the pits, but the point of delivery is changed frequently so that fresh sludge is discharged into digested sludge areas as much as possible. When a pit is filled it is allowed to stand and the supernatant withdrawn, or allowed to overflow as fresh sludge is pumped in. When it is filled as much as possible, it is allowed to stand idle and complete digestion as draining goes on. It is offered to farmers and market gardeners, being loaded onto their trucks free of charge with a clamshell rig. While the method of disposal has been cheap and satisfactory, it is not possible to dispose of all sludge produced, and when the space available is exhausted it will be necessary to provide some other method of disposal for at least a part of it. Digested sludge, as taken by the growers, contains from 75 to 85 per cent moisture, and on a dry basis, about 45 per cent volatile matter and 2.7 per cent nitrogen.

The quantity of water available for dilution of the plant effluent is very limited, White River reaching a low summer flow of 125 to 175 sec. ft. At low elevations the river consists of a series of pools and riffles. The outfall discharges into a pool behind a dam promoting the deposition of solids which flush out with subsequent rises of the river, resulting in toxic conditions lower down. The bacterial concentration in the river water is of no concern since it is used as a source of domestic supply only after some 125 miles of flow. It

is conceded, by all concerned, that the biologic action in the river may be utilized as a purification process in so far as may be possible without producing offense. With a capacity of the activated sludge plant which will permit the treatment of no more than 35 m.g.d., the oxygen of the river water is exhausted during periods of very low flow, and the problem then becomes one of removing the greatest possible poundage of organic matter regardless of the quality of effluent as measured in p.p.m. Insufficient settling basin capacity makes sludge concentration difficult and, to avoid excess volumes of returned sludge, a very low percentage of mixed liquor solids was maintained in 1931 and 1932. Gradually this practice led to the experiment of using no return sludge at all and it was found that a 60 per cent reduction of B.O.D. could be obtained in a reasonable aeration period. Much more volume can be accommodated under such an operation plan, and actually, a greater poundage of organic matter eliminated. Coagulation of solids occurs and, even at rather high rates of sedimentation, the sludge removed is very little less per m.g. than when using the conventional activated sludge process. The local advantage in this method of operation is

more pronounced in the cooler part of the year than in the summer. With a long period of experience as a guide, plain aeration was utilized in 1933 until the middle of the summer when the return of sludge was resumed for a period. The plant is now being operated without the return of sludge.

This method of operation has affected the unit cost prices very materially since larger quantities of sewage are handled, but imperfectly. In order to have comparative cost figures, the unit of "m.g." has been changed to "Thousand pounds B.O.D. Removed." On this basis, sewage has been treated at a unit cost more than 30 per cent less than by the regular activated sludge process. The plan is recommended only for a special situation as exists at Indianapolis at this time.

During the season of greatest capacity operation, and with the return of sludge, the plant is operated regularly at a cost under \$10 per m.g.

Average performance figures are available for the life of the plant and may be obtained by those interested in them.

A New Deal in Health Education*

BERTRAND BROWN

New York, N. Y.

THE other day I heard a man remark that undoubtedly the last stand of "rugged individualism" in this country would be in New York City among its 1,200 separate, independent social and health agencies. He hoped we were on the way toward communizing the industrialists, but feared that it would be a long and tedious task to socialize the social workers.

Abstractly, we Americans, and especially we social economists, go for the principle of coöperation "in a big way." Slogans proclaiming our faith are a commonplace of our daily existence:

United we stand, divided we fall.

Billions of reiterations on our seals, coins and currencies profess our faith in union on a par with our trust in God.

But not so our practice!

A commonplace of our very existence, continuously cited as our social salvation, our highroad to more abundant and glorious life, we who profess and are paid to be socially minded are prone to let it go at that—to substitute lip-service to the *principle* of coöperation for actual community planning, community organization, and community action.

There are few fields of our complex community life in New York City where this is more true than in that of health education.

The forty-odd agencies engaged in

health education in New York City have a natural penchant for doing things in their own ways. But this is perfectly human even if it is extravagant and costly. If the various departments of the municipal government, private agencies and professional and commercial groups engaged in health education in New York City could be brought to coöperate with singleness of purpose in a concerted attack upon the widespread ignorance of individual and community hygiene, the results of their present widely diversified activities would be greatly enhanced.

There is no wide difference of opinion about that. The way toward greater effectiveness in health education in the City of New York is stamped upon every penny of the quarter of a million-odd dollars expended annually for this purpose in the city:

E Pluribus Unum—Create one program out of many.

Before discussing any set-up through which health educational activity in the city might be coördinated and made more effective, it may be profitable to consider what the job of health education involves. What specifically do we mean when we talk about health education? I like to define it in terms of the basic tasks it involves.

I. THE FOUR BASIC TASKS IN HEALTH EDUCATION

In any intelligently planned health educational effort, there are four fundamental considerations present.

* Address before the Health Administration and Education Section, The Welfare Council of New York, N. Y., April 30, 1934.

They may be indicated by the four-part question:

1. What ideas, images, and emotional appeals must be conceived, accumulated, arranged, set forth and produced, and
2. Transmitted through what medium, or by what means
3. To what audiences, in what locality or localities, in order
4. To accomplish what objectives?

Much confusion will be obviated by a clear understanding at the outset that *wherever*, *however*, and by *whom*—ever done, health education is a process which necessarily involves these four basic considerations.

Health education can be intelligently planned and, as a consequence, effectively and economically pursued, only when each of these four fundamental component tasks is considered, not only as a separate factor in the educational process, but in its relation to each and all of the other basic tasks present.

Whether we recognize them or not, these basic considerations are always present in all health educational effort, and not only are they always present; they are always interdependent.

a. *Objectives*.—In order of procedure, the first task in outlining a health education program of any character or kind for any district or borough, or for the city as a whole, is to define clearly and concisely the objectives of the proposed educational effort.

What is it that we are setting out to do?

Over a decade ago (May, 1923), in his last public address, the late Dr. Hermann Michael Biggs suggested 11 objectives for practical present-day public health effort. Five of these were largely dependent for realization upon measures of mass education. Coming from this authoritative source of yesterday, we will cite them here as challenging general objectives for a city-wide program of health education for today. (But for our rugged individualism, all

of them might not still be pressing educational issues for today.)

The 5 of Dr. Biggs' eleven public health objectives, requiring health education for their accomplishment, were:

1. Establishing for every individual the custom of obtaining a periodic physical examination, made by a competent physician.
2. Further reduction in the death rate from the common infective diseases, such as tuberculosis, diphtheria, typhoid fever, scarlet fever, diarrheal diseases of infancy, and others.
3. Through physical examination and instruction as to methods for retarding or arresting their progress, postponement of the age at which death occurs from the cardiovascular diseases and other diseases of later life.
4. The prevention by education and law enforcement of new infections in the venereal diseases, and provision for more adequate treatment of syphilis.
5. The extension of the educational work of the public health authorities as a most effective means of promoting the preservation of health and the prevention of disease.

For practical purposes any or all of these ultimate objectives proposed by Dr. Biggs may be reexpressed in terms of more practical and immediate objectives. Each problem may be translated into terms of a 5-to-10-year plan. Each, moreover, can be expressed in terms of a sequence of particular activities, with first things put first, and with specific indication of what presumably can be accomplished day by day, week by week, month by month, and year by year.

Any set of objectives chosen can be thus translated into next things to be done. But it is only by clearly outlining as a first step the proposed objectives of an educational effort that such effort can be undertaken and conducted with that "intelligence in perspective" which will assure "accomplishment without vague and wasted effort," as Sydenstricker phrases it.

b. *Audiences*.—The second task in outlining a health educational effort of any character is to determine as clearly and concisely as possible who the indi-

viduals are upon whose mental attitudes and behavior achievement of the proposed objective depends.

Once the objective of the health educational effort is defined, it can be pursued *only* through communicating ideas, images, and emotions to individuals upon whose mental attitudes and behavior its attainment depends.

No problem in health education can be dissociated from specific individuals encompassed within the population. The individual is always the end of the effort.

The health educator should not only know *what* the problem is; he should know *where* it is and *who* has it. Only thus can he direct his efforts without waste upon those individuals and groups who most need them. Some problems are city-wide and can be attacked mass fashion across the boroughs. Other problems are local in character, and educational efforts directed at them can be wisely confined to a district, a neighborhood, a block, to selected racial or other groups, or to individual homes.

c. Ideas, Images and Emotional Appeals—The formulation and expression of ideas, images, and emotional appeals, which will achieve desired objectives with proposed audiences, constitute a third basic task in the health educational process.

Psychologists tell us that individuals can be motivated along prescribed courses to wished-for attitudes of mind and to fixed habits of action. Factors, present within the individual, are in a sense controls through which he can be motivated into desired behavior.

This knowledge is invaluable to the purposive mass educator. It means that once the objective and the audience are clearly in mind, ideas, images and emotional appeals constitute the ammunition of the educational task; that success is dependent in a large measure upon the authentic, convincing and

persuasive quality of materials used.

Motivation of the individual into improved health behavior depends majorly upon the choice of ideas, images, and emotional appeals which, utilizing his innate drives, will influence his mental attitudes and behavior, and consequently secure his coöperation in attainment of the desired objective.

d. Media of Communication—The fourth basic task of the health educator is that of choosing from the manifold channels available the media which can be employed most economically and effectively to communicate information and impressions to the audiences which have been selected because they are composed of individuals upon whose coöperation achievement of the desired objective depends.

Any educational effort, to be economically and effectively pursued, must necessarily be directed toward individuals according to their accessibility through established channels of communication.

Any program of health education which relied upon direct contact with the individual and family would seem hopelessly inadequate in a community the size of New York. Even if practicable, personal contact may not offer the best means for those who know, to communicate information to those who do not know.

Media available for mass education in the City of New York afford a high degree not only of coverage, but of selectivity both in locality and in intimacy and directness of personal contact with individuals.

The City of New York has been called the center of the machine age. In no quarter of the earth's surface is the health educator offered a more elaborate range of choice in the media which he will utilize to communicate ideas and purposive impressions to individuals and groups. And nowhere can knowledge and proficiency in the

use of these media be utilized to better advantage.

These are the four basic tasks confronted in outlining and pursuing any health educational effort. And I am unable to escape from two conclusions with regard to them.

First, that any program of health education to be fundamentally sound must be considered in the light of these considerations which are always inherently present.

And, second, that failure to recognize the presence and interdependence of these fundamental factors, more than any other thing, accounts for the lag in the development and refinement of our health education services on a par with other important professional fields encompassed within the public health movement.

Because of their importance to our present discussion, I repeat that any sound approach in the formulation of a health education program for the City of New York would provide primarily for accomplishment of the four-part task indicated by the question: (1) What ideas, images and emotional appeals must be secured; (2) to transmit through what media; (3) to what audiences; (4) to accomplish what objectives?

These specifically are the tasks which any organization engaged in health education must equip itself to perform. Whether or not they are recognized, they are always present in any intelligently pursued educational effort. Moreover, I repeat—these four tasks are always interdependent.

Naturally, therefore, the setting up of an economical and effectual plan of health education for New York City would seem to resolve into the coordination of available resources through some type of organization which would be designed, equipped, and staffed to assume leadership in the performance of

this sequence of tasks, which, though highly specialized, are interlaced in an inescapable relationship.

II. AN INSTITUTE OF HEALTH EDUCATION

For the foregoing reasons, if we were able to start with a clean slate and formulate an entirely new deal in health education in the City of New York, we would perhaps create a central organization designed specifically (and perhaps only) to assume leadership in the carrying out of these functions.

We would reallocate present personnel and recruit new personnel on the basis of its aptitude for, and training and experience in the knowledge and technics implied in this sequence of tasks. And may I add that no one would have a voice in the administrative direction of this effort who was not appreciative of the necessary and important part which each of these basic tasks must play in the complete cycle of the educational process.

In the last analysis, the success of an organization depends upon the background, training and qualifications of the persons who maintain it, the staff which renders its services.

Obviously, two main divisions of effort, in addition to that of administration and financing, are required to maintain the functions above outlined—one to carry on the all-important research functions; the other to devote itself exclusively to the interpretation and dissemination of health knowledge.

His program of objectives and his texts and subject matter, the mass health educator will need to obtain from those whose primary concerns are fact-finding and the diagnosis and prognosis of problems in the field of public health. At the same time and from the same sources he should be informed of the relative needs of the various elements which compose the city's population. He should be told not only what the problem is; he should

be told where it is, and who has it. Prepared with a consciousness of the ultimate use to which it is to be put, the health administrator and his research assistants should hand this information to the mass educator on a silver platter.

Moreover, no field of public health effort offers the research worker a more gaping opportunity for service in setting up procedures for the measurement of results, than this field of health education. His is the bookkeeping function to determine the success or failure of any particular educational method employed, and to measure progress in the attainment of any prescribed objective.

Perhaps the occasion calls for a larger view of the size of the job that confronts us and for the consideration of a new institutional means for coping with it.

An adequate plan for interpreting modern knowledge regarding the prevention of disease and the promotion of personal and community health in the City of New York, would, in my opinion, envisage the existence of an institute of hygiene which would assume leadership in the development of a concerted health education program set up along the lines above indicated.

A committee of the American Public Health Association, of which Dr. Victor G. Heiser of the Rockefeller Foundation is chairman, and of which I am a member, has considered at some length the possibility of creating in New York City a central institute of health education. This committee foresees such a central institution for spreading health knowledge as being housed in a popular museum of hygiene.

This Museum of Hygiene would constitute the graphic and animated textbook of the Institute of Hygiene. That it would house exhibits, specimens, models, photographs, charts, and animated apparatus for health teaching, is taken for granted. But it would also

plan to make full use of, if not build its program around, such modern channels of popular education as the motion picture, radio and television, which would magnify its usefulness beyond present comprehension. Obviously, the importance of showmanship, of freedom from academic restraint, should be recognized if such an educational plan is going to be effectual in raising the health standards of the masses.

For a health education institute and museum which would be a cloistered reference source, maintained chiefly for the further enlightenment of already privileged groups, Dr. Heiser's committee has not much enthusiasm. For a vital living institution, a theater and active institute of hygiene, equipped to utilize all available media to extend its services to the masses, alert to whatever new channels of popular instruction the future may bring, and committed to maintain continual contact with those whom it would exist to educate, this committee has great enthusiasm.

That its discussions are not visionary, the committee is assured by sober like-opinions from other cities, where similar plans are being discussed—notably Chicago.

Visionary? Any group whose task involves the spreading of health knowledge, which has not become aware of the necessity in this day and age of planning its program and its equipment to meet the competition for attention which it confronts, has not adequately qualified itself for leadership in its field. I repeat—that the occasion calls for a larger view of the size of our job.

Just a word about finances.

We are addressing ourselves to the need for a New Deal and a better day in public health education in the City of New York.

Our text? "There is no wealth, but life."

The quarter-million dollars expended

annually for health education by member organizations of this section, is a pittance as compared with the sums utilized in propagandizing their constituency on the commercial fads and fallacies of health. It would not even pay for Amos and Andy.

More money must be made available to do the kind of a health education job that we are talking about. But health educators are not the ones to raise it.

If the health educator acquires proficiency in the knowledge and skills required in the practice of his profession, and if he efficiently and economically employs its principles and technic to a degree approaching adequacy to the opportunity which confronts him, he will have no time to raise the money required to maintain his efforts. That is a specialized function requiring its own technic and its own personnel.

It is high time that we made a clear distinction between money raising and health education; that we ceased to accept a scheme of financing as a program of health instruction. It is high time that we quit harking back to educational methods employed in the peek-a-boo shirt-waist days and recognize that we are confronted with new problems and the challenges of new competition commanding proficiency of a new and highly specialized character.

III. MOBILIZING FOR HEALTH EDUCATION

However effective any central institute of hygiene instruction may be, it will not eliminate the necessity for much of the important and essential health educational activity now carried on by various agencies in the city. And that would not be its intention.

The advantages, however, of these groups associating themselves in an

effort to unify their programs are obvious. The existence of the Welfare Council's newly created section on Health and Education is an evidence of the recognition of this principle on the part of its members.

It would seem timely for this group to consider the creation of some set-up or scheme of coördination through which the health education activities of the various departments of the city government and of the various professional groups, private agencies and commercial groups, may be correlated and brought into a unified program of health education.

While such an organization would naturally follow the lines of general health activity in which several groups are now engaged, orientation and direction of their efforts along the lines of the fundamental considerations above implied, would greatly simplify their problems.

The organization of a city health council, like that set up the other day in the borough of Brooklyn through the coöperative efforts of the borough Chamber of Commerce and of the Brooklyn Council for Social Planning, may be the appropriate means to this end.

The form of organization for such an association would seem an appropriate matter for careful study by this group. But any adequate form of organization proposed would certainly embrace all of the resources available for increasing the health knowledge of the city's population.

Any program adopted would include all of Dr. Biggs's 5 objectives, now 11 years old! And any operating machinery set up would be designed, equipped, and staffed to assume conscious leadership in the performance of all of the specialized tasks inherently present.

OUTLINE OF INSTITUTE ON MATERNAL CARE

VICTORIAN ORDER OF NURSES FOR CANADA

THE Victorian Order of Nurses for Canada was first requested by the Public Health Nurses of the City of Toronto (The Community Health Association) to arrange to hold an institute on maternal care in that city early in 1931. The object of the institute is to emphasize from the nursing viewpoint the importance of, and to teach what is adequate prenatal care; and how working in coöperation with the medical profession and through effective use of existing agencies to make such care available for every expectant mother. Medical advice is sought and appreciated in so far as teaching material is concerned. Some of the most essential points to be dwelt upon are the community relationships involved, the nurse's responsibility toward the medical profession and health officials, to expectant parents, and with regard to the education of the public as to the necessity of medical advice and follow-up throughout pregnancy.

It is considered quite probable that nurses in cities other than Toronto and whether engaged in institutional, private duty, or public health work, may be interested and that there may be requests to hold institutes in different parts of Canada.

The subject matter consists of general information with regard to maternal care and the part the nurse may well take in providing this care; the essentials of prenatal teaching; possibly two demonstrations on delivery and postpartum care, with plenty of time for questions and discussions.

It is better if possible to have various nursing groups interested because of the contribution they are able to make. A

Victorian Order nurse gives leadership, but at the final session a medical man attends to answer such questions as may be submitted to him. It is rather important that it be someone with a decided public health viewpoint and the nurse herself has largely made these contacts. The discussions run practically throughout 2 days which means that a nurse can scarcely engage in any other activity at the same time.

The usual plan is that locally those arranging for the institute assume responsibility for securing a room and the necessary equipment, make the local contacts and arrangements, and become responsible for registration and collection of fees, which are later turned over to the National Office. The fee is \$3.00 per person except where there is a registration of 30 or more, when it is reduced to \$2.50.

Nationally, the responsibility of the Victorian Order is to supply the person to direct the institute, pay her expenses, and supply any necessary teaching or demonstration material.

They do not put on an institute for less than 15 nurses and the limit is 40. As the sessions are usually held in the class room of a local hospital, the matter of equipment does not prove any difficulty. They supply the necessary teaching or demonstration material.

When a local group of nurses arrange for an institute they assume the responsibility of interesting the nurse, of registration, securing a place to hold the institute, collecting the fees, and turning them in to the national office; the Victorian Order of Nurses bearing all expenses apart from those already mentioned.

The nurse is an exceptionally well qualified person to undertake this work. She is a Canadian graduate, has not only had public health training and held positions as supervisor in the Toronto City Department of Health and National service of the Victorian Order, but has also had obstetrical, mothercraft training and experience in England and has more recently observed institute work as carried on by the Maternity Center Association, a specialized organization, in New York.

The Victorian Order of Nurses for Canada welcomes the opportunity of extending its field of usefulness. In working out the plan briefly outlined above it is hoped to evolve something truly Canadian in character which will result in more intelligent, uniform, and

effective teaching being given, and through bringing representative nurses together for conference and discussion under leadership, should strengthen the relationship between medical and nursing professions; and eventually through the interested health and social agencies represented and working toward this end, prove a valuable contribution to the welfare of the mothers and future citizens of the country.

Good prenatal care is nothing but the proper foundation for good natal attention. Neither is complete in itself, and if either is inadequate, both may result in failure. . . . It is only during pregnancy that the proper preparations can be made for the all important natal and post-natal care. . . . Prenatal care is not an end in itself but only a means to an end (Dr. Fred Adair).

SECOND ANNUAL REPORT OF THE DIRECTORS OF THE H.S.P.A.-EWA PLANTATION HEALTH PROJECT

MARTHA R. JONES, PH.D.

May 31, 1933, marks the close of the second year of the plantation "Health Project" which has been conducted jointly by the Ewa Plantation Company, the Hawaiian Sugar Planters' Association, and the Research Department of Queen's Hospital, Honolulu. A brief review of the activities undertaken and accomplishments to date is herewith submitted.

INFANT FEEDING CLINICS

In July, 1932, "health centers" were opened in "C" and "Lower" Villages, making a total of 4 "centers" which cover the entire plantation. All cooking is done in one center and the milk formulas and other foods—ready to be served—are delivered to the other centers where the babies living in the surrounding districts are brought once daily and fed. Formulas for other feedings are taken home.

Enrollment of babies in the Health Center is voluntary with parents and they pay a flat fee of \$1 per month for each child. An additional charge is made for extra food over the amount allowed for the \$1 enrollment fee. During the past year the receipts from parents covered approximately three-fourths of the cost of the food.

ENROLLMENT AND ATTENDANCE

Number of babies enrolled June 30, 1933	225
Per cent enrolled of those eligible (birth to 2 yrs. of age).....	92
Daily attendance (per cent of those enrolled)	85

The age limit of 2 years for enrollment in the feeding clinic was removed during the year. When there is one child enrolled in the Health Center, parents, in general, object to enrolling the new baby unless the older one is discharged. The excuse is invariably

"expense." The need for increasing the age limit for enrollment is shown in the marked reduction in growth rate and increase in dental decay in those children who have been discharged at 2 years of age. Few parents know what constitutes normal development in babies and children and they accept poor posture, sunken chests, flat heads, thin bodies, bowed legs, diseased tonsils, decayed and abscessed teeth as inevitable and with little or no concern. Those babies who have been largely or exclusively fed on food provided by the Health Center are outstanding in physical development. . . .

MORBIDITY

General—Infant health has improved, as has that of the preschool children. There have been few cases of pneumonia, with only 2 deaths (1 infant with whooping cough and 1 preschool child following measles) in more than 2 years. There has been no death from diarrhea and enteritis since the health project was started, and no case among infants that warranted hospitalization in more than a year. Mothers have learned how to prevent beriberi, and there has been no case which could be diagnosed clinically during the past year. The incidence of impetigo, pink eye, and ear infections has been comparatively low. Illness is to a large extent restricted to the children of noncoöperative mothers. . . .

Venereal Disease—There are a number of families on the plantation, various members of which show clinical or other evidence of syphilis. Eight of 9 Filipino women thought to be diseased, whose record is 81 pregnancies, have given birth during the past year or are now pregnant. There are 6 living babies, all of whom received some anti-syphilitic treatment. The expectancy of life in all cases is good; nevertheless, 2 of this number already show marked clinical evidence of the disease. They

are all offspring of alien parents, most of whom are too ignorant or indifferent to practise birth control. It is doubtful whether permanent cures are ever effected in syphilis, and in all probability, some, if not a considerable number, of this group will eventually become public charges. . . .

Dental Decay—Dental decay is a systemic disease. "Odontoclasia," a type of dental decay which is ravaging the teeth of the babies and young children of Hawaii, is a sensitive, and probably the best, indicator of community health. It is associated with high infant mortality, diseased tonsils, stunted growth, susceptibility to disease, and abnormal development of the jaws, nasal and other facial bones, which often lead to a succession of ills which persist throughout life.

Odontoclasia has its beginning in prenatal life. It may occur in unerupted teeth and even in the teeth of the unborn. In a group of 50 Ewa Plantation Oriental babies studied before the health project was started, 40 had decayed teeth at 1 year of age, and 49 at 2 years. Odontoclasia can be prevented and arrested by diet—and apparently in a very simple way—the substitution of taro and potatoes for grain foods.

Concomitant with the tremendous and continuous reduction in infant mortality and morbidity on the plantation during the past 3½ years, there has been a parallel reduction in the incidence of odontoclasia. . . .

EDUCATION

Baby Conferences—In addition to the feeding clinic which is held daily, conferences with mothers during which each baby is weighed, measured, examined, and his teeth charted are held bi-weekly. In addition to advice as to general care, mothers are instructed in regard to the kind and amount of food needed for their babies. An effort is

made to examine all babies under 1 year of age at least once each month.

Prenatal Clinic—Mothers are being taught by means of X-rays of the bones of new-born babies and other tests that the diet of the mother during pregnancy has a marked effect upon the bone and tooth development of her child. They have learned something of the anatomy of their own bodies, how the fetus grows, and the principle of birth control. As a result, the babies are being born with a better start in life. Fewer babies were born the past year than in any preceding year—97 as compared with 119 in 1932. . . .

Medico-dental-social-economic Research—The Ewa Health Project is the clinical application of at least 12 years of medico-dental research. Its ramifications include already social and economic aspects which may be far reaching in significance. An analysis of conditions as they used to exist in Hawaii and as they are today, and the interpretation of the findings in the light of scientific knowledge and animal

experiments, lead to the conclusion that a return to the type of diet employed by the ancient Hawaiians will automatically solve many of the economic-health-social problems of the community. A basic principle of nutrition which has to do not only with health, but life itself, is involved.

Can grain eating people from foreign lands be induced to eat native foods—particularly taro and sweet potatoes? They have to be taught. When doctors, nutrition teachers, cafeteria directors, social workers, and those who have to do with the feeding of others accept the fact that taro and potatoes have a very special value in the diet in the tropics and are not interchangeable with grain foods, much progress will be made. It is a new idea and has to be demonstrated. Ewa is staging the demonstration, and is doing it in an ideal way—the people making the demonstration pay and profit; the plantation profits; the community profits; the world and the millions of people yet to be born will profit. . . .

ATTENDANCE OF MEMBERS AT ASSOCIATION ANNUAL MEETINGS

THE Medical Officer, England, has this to say in its March 31, 1934, issue concerning the American Public Health Association.

"In America . . . cohesion and interdependence of all local units hardly exists. The Federal Government has certain powers over all the States, the States over the counties, and the counties over the smaller communes, but all these units are in the main independent. The American Public Health Association is the chief body in promoting unity of design and action. It has no power save that of persuasion, but this in a body so comprehensive and united and so efficiently organized is powerful, if not compelling."*

There is one short period in the year when the powerful and compelling influence of the American Public Health Association is at its apogee. That is during the time of its Annual Meeting, when it is truly on parade and the world of public health and preventive medicine watches with interest for its pronouncements, knowing well that the course of public health will be affected by what transpires during that time.

The Association is, of course, its membership, the 4,300 public health workers from every state in the Union, from Canada, Cuba, and Mexico, representing federal, state, county and city health departments, and every type of agency directly or indirectly concerned with health and welfare.

The Annual Meetings of the Association presumably reflect the interests and activities of its members. The Annual Meeting presumably presents to the world the story of public health achievement of Association members during the previous twelvemonth, and points the way for the succeeding twelvemonth; yet at such

* See page 809 for complete article.

an important time, only a small percentage of that membership is on the scene and takes part in the deliberations.

At the Sixty-second Annual Meeting in Indianapolis in 1933, the registration was nearly 1,000. An analysis of attendance, made with a view to determining section participation, follows:

	<i>Total Membership of Section</i>	<i>Number of Members Registered at Indianapolis</i>	<i>Per Cent at Annual Meeting</i>
Health Officers	922	143	15½
Laboratory	513	101	19½
Vital Statistics	99	23	23
Public Health Engineering	407	60	14½
Food and Nutrition	210	32	15
Industrial Hygiene	145	24	16½
Child Hygiene	344	56	16
Public Health Education	456	53	11½
Public Health Nursing	436	49	11
Epidemiology	106	32	30
Unaffiliated	642	43	6½
Total	4,280	616	14

By subtracting 616 from 1,000, we find 384 guests were present. Most of these were professional public health workers, it is true, not affiliated with the Association, however, as members. It should be stated at this point that guests are expected and warmly welcomed. May the Pasadena Meeting bring us many more than 384. Nevertheless, it is highly important that the number of members in attendance be in greater proportion to non-members than three to two.

The attendance at an Annual Meeting of only 14 per cent of the total membership is not as it should be. The policies of the Association itself are shaped during the Annual Meeting; officers are elected; and resolutions adopted committing the entire Association to certain principles—these important things should be acted upon by more than one-seventh of the organization's constituents.

The advantages of membership in the Association have been described many times, most emphatically by members themselves. The membership, even in a time of depression, holds up as remarkably as the health of the country. That fact, in itself, is proof that the member finds his connection with "a body so comprehensive, united and so efficiently organized" worth while. The advantages of attendance at Annual Meetings are obvious to the several hundred members who return again and again, it having been demonstrated to them that they cannot afford to stay away. Other hundreds should realize that their identity with their profession means more than the payment of annual dues and a monthly scanning of the JOURNAL. The Annual Meeting is for them, for every member, offering to them the opportunity to make themselves felt and heard for their own ultimate good, the good of their profession and the public health movement.

The Association will be on parade again from September 3 to 6 in Pasadena. Elsewhere in this issue appears the preliminary program which needs no word of editorial commendation, since it speaks eloquently for itself. Let us, as members of the Association, attend the meeting in full expectation of personal enrichment and in such numbers that the full purpose of the Annual Meeting is abundantly achieved.

THE DEPRESSION AND PUBLIC HEALTH EXPENDITURES

IT is not news to those interested in public health, and especially to health officers and health workers generally, to know that the expenditures for health throughout the United States have been cut down to a dangerous degree on account of the depression. According to what are believed to be reliable statistics, in 1929 the average expenditure for public health in American cities was \$1.00 per capita per year. For 1934, the expenditure will be a little more than \$.70. In some cities as well as states the cuts have been so great as well nigh to destroy the efficiency of the health organizations. In certain cities the health budget has been reduced very much out of proportion to the revenue of the city. In the city of Birmingham, Ala.,¹ for example, while the revenue has declined 27 per cent, the health budget has been cut 64 per cent. The appropriation for Parks and Recreation has been cut 10 per cent; for Library 40 per cent; for Police Department 42 per cent; for Fire Department 34 per cent—that for the Health Department 64 per cent!

While Birmingham has never been noted for its large per capita health budget, in 1915–1916 it was reduced to \$0.155 per capita per annum. There followed the typhoid epidemics of 1916–1917, and those who studied these outbreaks were convinced of the connection between the decrease in money and the increase of disease. In 1928 the citizens of Birmingham seemed to have been sold on the public health department on account of the good work which was evident to them. They apparently became so well satisfied with the organization and operation that they dismissed the matter from their minds. The depression developed and, as in all such times, health problems increased tremendously, in spite of which, the health organization has been badly crippled by lack of funds.

An example of what has taken place is the food handling establishments, of which there are some 2,000 in the city of Birmingham. Each one has a certificate assuring the public that it has been inspected from the health standpoint and the citizens are still patronizing these establishments with the confidence that the certificates they exhibit mean something. As a fact, the Department of Health has been reduced to a point where there are only 2 food inspectors to cover the entire 2,000 establishments. Is it possible that 2 men, however efficient and however honest, can cover so many establishments? We believe not.

Another example is in the public health nursing service. It is generally accepted that there should be 1 public health nurse on the average for each 2,000 people. The force in Birmingham has been so reduced that each nurse has 23,000 people to care for.

Birmingham is not the only city in the United States which is suffering. The cut in health funds has been very general and very deplorable. In some cases unfortunately politics seems to be playing a part also. Never has there been a time when efficient health work was more needed than at present. It is true that we have been blessed with a succession of years characterized by good weather and a marked absence of epidemic diseases. Only here and there have there been outbreaks and, with the possible exception of measles during the spring of 1934, these outbreaks have been localized, and not extensive even in the communities in which they occurred.

We have always believed that public health was a good deal like religion.

In the face of danger we turn to a higher power and become very devout. We wrestle mightily in prayer with the Lord when epidemics decimate our population, when droughts occur cutting off our food supplies, or when floods destroy our growing crops, but when things go well, the human mind is such that it forgets danger. We are very much like the little boy who said his prayers regularly at night, but not in the morning on the ground that he could take care of himself during the day time. This has been expressed aptly in the old quotation:

"The devil was sick, the devil a monk would be,
The devil was well, the devil a monk was he."

1. *Birmingham's Health*, The Jefferson County Board of Health, Feb., 1934.

AMEBIC DYSENTERY IN CHICAGO

THERE are many reasons why the outbreak of amebic dysentery in Chicago in 1933 still holds intense interest. Some of these are practical and some scientific. On the practical side it will be recalled that the Exposition for 1934 opened in May. Already some of the daily papers are asking whether precautions have been taken to make the city safe for visitors, and repeating the charge that the news last year was suppressed. On the scientific side it must be pointed out that, as far as we have been able to determine, this is the first epidemic of the sort which has ever been recorded. The health officers had an entirely new problem to deal with, and there is no question that it took them by surprise, as it did everyone else. The paper read before this Association on October 9, 1933,¹ attracted little attention; so little, in fact, that a prominent officer of the Public Health Service who heard it went back to Washington and did not even mention it. Some days later the report of a physician in Indianapolis that there were 5 or 6 cases of the disease in that city, all traceable to Chicago, gave the first intimation of its seriousness. Following this, on November 25, came from Boston² what was probably the first information which showed how widespread the infection was, cases in Canada and elsewhere being reported. There was no official publication from the Board of Health of Chicago, as such, until November 18,³ though on November 14, the radio was used.

The health authorities of Chicago have been blamed severely for suppression of the news and it has been charged that it was done in order not to scare visitors away from the Exposition.

A careful and what we believe to be an unbiased investigation fails to substantiate such a motive, though the facts are as just stated.

It must be remembered that very few of these cases occurred in Chicago, two having been reported on August 16, the date which the authorities fixed as the beginning of the outbreak. Owing to the period of incubation, which has been fixed by several observers on epidemiological evidence as from 12 to 30 days for the majority of cases, and even longer for others, visitors had arrived home in Canada and various parts of the United States before being taken sick. Doctors have all been taught that amebic dysentery is a tropical disease, and were not looking for it. Various diagnoses, such as appendicitis, colitis, ulcerative colitis, etc., were made. Operations for appendicitis were entirely too frequent, and the evidence shows that the majority of deaths have occurred among those who were operated on under mistaken diagnoses. Up to January 24, 1934,⁴ 721 clinical cases of amebic dysentery in 206 cities have been found and traced to Chicago,

in addition to which, 1,049 carriers have been found in Chicago. Ninety-four per cent of the cases detected were guests at either Hotel C or A. Hotel A obtained its water from a tank on the roof of Hotel C. This water had been used for cooling and air conditioning purposes before being pumped to the roof. On January 22, a committee met in Chicago for 6 days and heard reports. Their conclusions have entirely changed the picture if they are accepted. In the meantime engineers have studied the situation, and several men who are specialists in the study of tropical diseases have been called upon.

As early as November 22, the hotels incriminated were directed to improve their plumbing arrangements. The Board of Health has had some 15 engineers or technical assistants making an intensive study of the water and sewage systems of the hotels involved. It must be said that they were in a mess. Like Topsy, the system has just "grewed," without noticeable planning. The house engineers have been in the habit of making repairs and additions without notifying the city. The inspection of hotels is not what it should be. Several city departments have inspectional powers, such as the Building Department, Fire Department, License Department, Department of Gas and Electricity, Smoke Inspection Department, Department for the Inspection of Steam Boilers, Department of Public Works, and Board of Health. It would seem that concentration of responsibility might have led to better results. Since the depression and the bankrupting of the city by the former administration, there is a shortage of inspectors, and even new work is scarcely kept up with, much less watching old work, repairs, alterations, etc. The evidence is that two hotels were responsible for 94 per cent of the cases detected. Careful charts have been made showing the dates of registration of the visitors and the dates when their bills were paid, as well as the appearance of the symptoms and the course of the disease as far as possible. If any considerable number of cases have occurred in the city, they have not been detected.

The hotels involved have been ordered to rearrange entirely their plumbing systems and to install new works throughout. The older part of the chief hotel dates back to the time when steel pipe was considered the best material for such work. The sanitary sewer pipes were found to be badly corroded, so that the writer pushed a five cent kitchen fork through the main pipe. Many leaks existed and, in a number of places, wooden plugs now badly rotted had been used to stop holes. Unfortunately, the sanitary sewer which carried some 62 per cent of the load of the hotel passed directly above the tank in which water was refrigerated for the dining rooms and the floors. The ice machines, the laundry, the machine shop, the room for the preparation of the desserts, etc., were all on the same floor and were below the level of the street sewer. Two 4 inch sewer pipes intended for overflow emptied into a cement trough under the laundry tubs. All leakage was carried to sumps and forced to the level of the street sewer.

The committee mentioned found that following two rains on June 29 and July 2, the street sewer broke, flooding the basement of Hotel C and running directly into the ice storage house. In their report a good deal of stress was laid on this, but the epidemiological evidence collected since shows that following this accident there was a remission of cases for approximately 3 weeks, which the engineer in charge attributed to improved drainage!

The numbers of carriers and active cases, most of whom worked in the basement of Hotel C, has been repeatedly given.⁴ It seems that the committee approached the question with a firm conviction that the disease was due to carriers and active cases among food handlers, and there is little doubt that the great majority of

people who have studied the question have believed in the same origin. Leaky sewers and cross-connections and a generally bad condition of plumbing would have furnished the means of spreading the infection. Great doubt has been thrown upon this method of origin by the investigation of Spector and Buky.⁵ The drying of the amebae rapidly destroys them—a matter of minutes. In an experiment on this point, the hands of doctors were painted with a thick emulsion of feces rich in cysts. Drying for even a few minutes destroyed them, as tested by the vital staining which protozoölogists hold constitutes an accurate diagnosis between living and dead organisms, the living cysts refusing to take aqueous eosin, while the dead ones absorb it readily. These experiments seem to do away in great measure with the carrier question; but it does not entirely absolve food handlers who are carriers and serve salads which are sent up in a moist condition.

There are still many problems to be answered. What, for example, is the relation between the large cyst and the small cyst? Some of our best known authorities claim that they are the same, but Dr. Spector finds that she can cultivate the large cysts without trouble, whereas failure attends the great majority of her efforts on small cysts. On the face of it, this would indicate some difference in the two organisms.

Certainly the studies in Chicago will compel us to rewrite our chapters on amebic dysentery. The committee referred to acknowledges that there is much room for study and, while we deplore the tragic events which have made this investigation necessary, there is little question that in the end, all health officers in this country as well as others, will be in a better position to avoid such outbreaks in future and to handle them when they occur.

A symposium on the subject was a feature of the meeting of the American Medical Association in Cleveland in June, and for our own meeting in Pasadena in October a discussion has been arranged.

EAST AND WEST SHALL MEET

LONG ago, the poet said—

“For East is East
And West is West;
Never the twain shall meet.”

Fortunately, this does not apply to public health workers, for those in the East and those in the West speak the same language, uphold the same traditions, carry the same burdens, strive for the same results, and they meet together at least annually for purposes of mutual advancement and development. Public health workers of California and other western states are gratified at the prospect of the Sixty-third Annual Meeting of the American Public Health Association in Pasadena. There is a traditional pride in serving as hosts to the public health workers of the nation, and there is a sense of appreciation in the opportunities for acquiring knowledge through practical experience and instruction provided by leaders in the profession who come from older communities and institutions. Meeting in a far

western state tends to break down all provincialism, for sectionalism is rare in the free atmosphere of the rugged West.

It is little more than 80 years since oxen-drawn, covered wagons were dragged across the overland trails to California, and it is little more than 60 years ago that the first railroad train brought passengers to California. In 1934, visitors come to the Golden State on luxurious trains, comfortable buses, fast airplanes, and in privately owned automobiles. It required many weary months of travel for covered wagons to cross the Rocky Mountains, plains, and the deserts. Fast trains now cover the same routes in 3 days, while airplanes soar over the old overland trails within a few hours. Time and space are almost annihilated and costs of transportation have become almost negligible.

There is much of interest to public health workers in California. Fifteen full-time county health units can be visited by automobile within a few hours. An excellent system of perfect highways connects all of these places of interest. There are at least five higher institutions of learning that are worthy of visiting—the University of California and the University of Southern California at Los Angeles, the California Institute of Technology at Pasadena, Stanford University at Palo Alto, and the University of California at Berkeley.

The Yosemite Valley, with its many waterfalls and granite peaks, the Sequoia National Park, with its marvelous big trees, Lake Tahoe, nestling mile-high among the pines of the Sierra, the Redwood Highway—a paved road between enormous redwood trees—skirting the northern California coast, the old missions scattered from San Diego to Sonoma, the famous Seventeen-Mile Drive at Monterey, the Rim of the World Drive and high Sierra lakes in the mountains of Southern California, the motion picture studios at Hollywood, the Mexican settlement at Agua Caliente, and dozens of other attractions will provide recreational facilities to please every guest. California bids you partake of its western hospitality!

ALVAH HUNT DOTY

DR. ALVAH HUNT DOTY, member of the A.P.H.A. since 1896, and a Charter Fellow, died on May 28 at Pelham Manor, New York, at the age of 79. He was born in Albany, graduated from the high school there, and afterward attended the Rochester Military Academy. His degree in medicine he received from Bellevue Medical College in 1878.

Appointed an inspector on the staff of the Health Officer of the Port he subsequently was made diagnostician of the New York Board of Health, and then chief of its Bureau of Contagious Diseases.

He was appointed Health Officer of the Port of New York on January 2, 1895, by Governor Morton, through which he became also a member of the Board of Health of New York City. As Health Officer of the Port, it was his endeavor to facilitate commerce and to keep out communicable diseases from the City without unnecessary delay, and with as little inconvenience to merchants and passengers as possible. His writings testify to his scientific attainments and broad knowledge of medicine.

In 1913 he was appointed by Theodore N. Vail Medical Director of the Employees Benefit Committee of the American Telephone and Telegraph Company, the Western Union Telegraph Company, and the Western Electric Company. Here he continued his investigations, writing on "The Care of Tuberculous Employees by Corporations as Employers." This was followed by "The

Value of Examinations of Applicants for Industrial Employment," 1916; "Poliomyelitis," 1917, "Outlook and Problem of Public Health," 1919; "Typhus Fever and Quarantine," 1921; "Common Sense in the Prevention of Influenza," 1922.

Among the measures of preserving health Dr. Doty expressed his views in a book *Walking for Health*, published in 1924.

To the Bulger charges in 1911, made in a spirit of hostility, Dr. Doty's defense in the *New York Times*, December 7, fully covers the matter. These charges were petty and did not constitute sufficient reason for the action taken by Governor Dix. He was defended in this matter by a number of the ablest and best known physicians in the City of New York.

Dr. Doty was a tireless worker. He usually arose at 5 o'clock in the morning, and gave himself unsparingly and with unfailing energy to the work of his profession. His highest pleasure was in service.

He had confidence in himself and rightly so, for he was well equipped and peculiarly fitted for the service he engaged in, always giving the closest attention to even the smallest details. There was no branch of sanitary science with which he was not familiar. In his medical relations he was ethical and invariably spoke well of others, never envying anyone his success.

He was sincere, with a fine sense of honor, cheerful, of engaging personality, interesting in conversation, with much humor, enjoying his friends. He was moderate in his habits, a loyal friend, and devoted husband and father. Because of his modesty, the credit of much of his work was given to others.

TWELFTH INTERNATIONAL VETERINARY CONGRESS

A MOST interesting event will be the Twelfth International Veterinary Congress to be held at the Waldorf-Astoria Hotel in New York from August 13 to 18. It will be under the patronage of President Roosevelt, but the scientific president of the Congress will be the noted Professor E. Leclainche, Director of the Bureau of Epizootics, Paris, France. From England will come Sir John M'Fadyean and practically every country in the world will be represented by men prominent in the veterinary profession and in the sciences related to it.

Among those who have promised to be present and to give papers are Ramon of toxoid fame, Bang of Copenhagen, who has done so much in tuberculosis of cattle, Guérin who was a coworker with the late Professor Calmette on BCG, and many others. Although the program has not yet been published, there is an assurance of an abundance of material of scientific interest to physicians in general as well as to the veterinary medical profession and to laboratory workers.

There is every reason why the medical profession, especially that branch of it devoted to public health, and the veterinary medical profession should act in concert with each other. Every year shows the diseases of animals which are transmissible to man or which are carried by animals to man. It has been the wish of the writer for many years to bring the two professions more closely together. Here is an opportunity of which our public health workers should avail themselves gladly. Since the Congress will be held in New York, it will be easy of access to a large part of the public health workers in our country.

Further information can be obtained from Dr. H. Preston Hoskins, 221 North LaSalle Street, Chicago, Ill.

INDUSTRIAL HYGIENE

Seventh International Congress on Accidents and Industrial Diseases, Brussels, 1935—This Congress is to be held in July, 1935, under the leadership of Dr. Glibert. The object of the Congress is to coördinate the work of the Permanent Commission on Occupational Accidents and that of the Permanent International Commission on Industrial Medicine. The program of the Congress will consist of official reports on questions which have been placed on the agenda and also independent reports on the same subjects. The program has been divided into three sections, each of which will deal with two questions:

A. Surgery:

I. Delayed effects of injuries to the cranium

II. Traumatism of the hand and fingers

B. Occupational Diseases:

I. The prevention of industrial dusts

II. Pathologic action of gases escaping from burning veins in coal mines

C. Joint Session:

I. Objective manifestations of pain

II. Electricity

A number of participants have already signified their intention of giving papers—two from this country, Dr. R. R. Sayers and Dr. Yandell Henderson, who will report upon the physiologic and pathologic effects of coal mine gases. Additional papers are invited from all countries.

For further information address Dr. Fred H. Albee, 57 W. 57th Street, New York, N. Y., who has been appointed American President of the National Committee for the Section of Accidents,

or Dr. Emery R. Hayhurst, Chief, Division of Hygiene, State Dept. of Health, Columbus, Ohio, who is American President of the National Committee for the Section on Diseases.

Prize Offered by the Congress in Geneva—The following announcement has been received from Dr. L. Dejardin, Secretary-General of the mentioned Congress, Brussels:

1. The committee of organization of the Sixth International Congress on Occupational Accidents and Diseases, held in Geneva in 1931, established a prize of 1,000 francs to be awarded to the author of the best work, original and unpublished, on the subject "The Importance of Previous Physical Condition in Estimating the Sequelae of an Industrial Accident."

2. Physicians of all countries are eligible to compete for the prize.

3. The prize will be awarded at the coming Seventh International Congress which will be held in Brussels in July, 1935.

4. Typewritten manuscripts in two copies must reach the Secretary-General of the Congress, in Geneva, before December 31, 1934. They may be written in French, English, German, or Italian.

5. The author will retain ownership but must publish it in the year following the award of the prize.

6. The jury will be composed of the committee of organization of the Congress of Geneva.

7. The manuscripts should not be signed, but should carry a symbol, which is to be reproduced on a sealed envelope containing the name, address, and titles of candidate.

Correspondence regarding the above may be addressed to Dr. Fred H. Albee, 57 W. 57th Street, New York, N. Y., or Dr. Emery R. Hayhurst, Ohio Health Department, Columbus, who are the chairmen of the American committees, surgical and medical, respectively, representing the Seventh Congress.

Industrial Safety and Health Standards—A committee to consider standards for the safety and health of industrial workers, for application to the codes of fair competition promulgated by the National Recovery Administration, was appointed in February, 1934, by Secretary of Labor Frances Perkins. The permanent committee established consists of representatives of the following organizations:

- American Federation of Labor
- American Standards Association
- National Bureau of Casualty and Surety Underwriters
- National Recovery Administration (one representative each from the Administrative Division, Consumers' Advisory Board, Industrial Advisory Board, Labor Advisory Board, and Legal Division)
- National Safety Council
- New York State Department of Labor
- U. S. Chamber of Commerce
- U. S. Department of Commerce, Bureau of Standards
- U. S. Department of Labor
- U. S. Department of Labor, Bureau of Labor Statistics (one representative each from the Division of Accident Statistics and the Labor Law Information Service)
- U. S. Department of the Interior, Bureau of Mines
- U. S. Department of the Treasury, Bureau of Public Health Service

As a result of the deliberations of the committee and on recommendations by the Secretary of Labor, the National Recovery Administrator directed that the following provisions be included in every code which had not been formally submitted by the industry on March 14, 1934:

Every employer shall provide for the safety and health of employees during the hours and at the places of their employment.

Standards for safety and health shall be submitted by the code authority to the administrator within 6 months after the effective date of the code.

The manner in which these provisions, which are now embodied in most codes, will be given execution, is next briefly outlined.

(In examining the list of representative organizations and the provisions for execution, the editor feels that health and hygiene have not been given proper weight or hearing, and calls attention to the findings of Dr. C. O. Sappington in his investigation of the sickness and accident experience in the Edison Electric Illuminating Company of Boston, reported in the *Journal of Industrial Hygiene* for July, 1924 (Vol. VI, No. 3, p. 94):

Since the Edison experience has shown that sickness causes twenty times as many cases of absenteeism as accidents and is responsible for seven times as much loss of time from work, it would seem rational that any program for solving the problem of lost time would give results if money was intelligently used to further disease prevention. This does not mean that vigilance should be relaxed in the slightest degree in attempting to prevent accidents. Accident prevention has received so much attention in the past, however, that it now seems evident that emphasis might profitably be placed on earnest attempts to thwart the inroads of disease in industrial establishments.

Proposed Industrial Medical Code in the United States—The American College of Surgeons has submitted to the National Recovery Administration in the United States a draft medical Code for industrial employees.

The general principles of this Code include the proposals that all new employees should have preemployment examinations and all employees annual health audits by doctors employed by the industries; that industries should establish individual or joint pathological and X-ray laboratories, that defects revealed by examinations be treated at the cost of the industry in so far as they come within the scope of workmen's compensation or other State laws, and otherwise be referred to the family physician of the employee, who should be provided with the records and facilities of the industrial laboratories at minimum cost; that the facilities of the laboratories should be available to the family physician for the care of the families of employees.—

Indust. & Labour Inf., 49, 13:435 (Mar. 26), 1934.

Eye Protection in Industry—This pamphlet includes a self-appraisal for safety engineers and plant managers. It is estimated that at least 15 per cent of the blind of America lost their sight because of occupational hazards.

More money is paid by employers each year as compensation for eye injuries than is paid for injuries to any other part of the body. This totals \$10,000,000 a year in the principal industrial states, but this cost represents only part of the picture. Thus, the Travelers Insurance Company found that the indirect cost to industry of accidents is generally four times as great as the direct cost.

The chief eye hazards of industry are those due to accidents, diseases, and excessive eye fatigue. (The methods of prevention of each of these are briefly detailed.)

The self-appraisal form is arranged to check and give values for each type of protection found to exist against eye hazards. The first part of the appraisal concerns the plant, the second part, the worker, and the third part, the job.—Louis Resnick, National Society for the Prevention of Blindness, Inc., *Publication No. 77* (50 W. 50th Street, New York, N. Y., Price 5¢).

An Unusual Case of Pneumoconiosis—The authors report, in some detail, a case of dense, bilateral pulmonary fibrosis which developed rapidly in a man, aged 48, who had been a construction foreman in a tunnel project for one year. The dust, from a white rock of undetermined composition, was very dense, and drilling had been done without the use of water or masks. The symptoms began about 15 months after the exposure ceased. The man's occupation for about 18 years had been concerned with grading roads, in rock quarries, and laying concrete. The X-ray and autopsy findings seemed typical of acute silicosis. The silica

content was 50.5 of the dry lung ash.—George F. Grisinger, T. R. Boling, and Bert Bradford, *West Virginia M. J.*, 29, 10:436–38 (1 ill. of lung roentgenogram) (Oct.), 1933.

Major Articles in the Journal of Industrial Hygiene—The March, 1934, issue, Vol. 16, No. 2, contains the following:

The determination of mercury in air and in urine. A. M. Fraser, McGill University.

Mercury-laden air: Toxic concentration, proportion of mercury absorbed, and urinary excretion. A. M. Fraser, K. I. Melville, and R. L. Stehle, McGill University.

A rapid method of dust sampling and approximate quantitation for routine plant operation. Theodore Hatch and E. Ward Thompson, Harvard School of Public Health.

An appraisal of the lead hazards associated with the distribution and use of gasoline containing tetraethyl lead. Robert A. Kehoe, Frederick Thamann, and Jacob Cholak, University of Cincinnati. "There is no reason to fear the existence of danger to the public health from the distribution and use of leaded gasoline."

The effects of the inhalation of hydrogen fluoride. I. The response following exposure to high concentrations. Willard Machle, Frederick Thamann, Karl Kitzmiller, and Jacob Cholak, University of Cincinnati.

The book reviews refer to *Industrial Chemistry, An Elementary Treatise for the Student and General Reader*, by E. R. Riegel, University of Buffalo, pp. 784, 233 figs., 2nd ed., New York: The Chemical Catalogue Company, Inc., 1933. Also, *Workmen's Compensation for Silicosis*, Report of the Committee on Pneumoconiosis, A.P.H.A., paper, pp. 39, Assn. of Casualty and Surety Executives, New York, 1933. The usual abstracts of industrial hygiene literature complete the issue, pp. 25–42, followed by an author index for the abstracts.

The May, 1934, issue, Vol. XVI, No. 3, contains the following:

A cause for the decrease in the number of ions in air of occupied rooms. G. R. Wait, Carnegie Institution of Washington.

The action of mica dust on pulmonary tissue. A. Policard, University of Lyon (France).

Roentgen technic with especial reference to the examination to diagnose or exclude silicosis. Henry K. Pancoast, and Eugene P. Pendergrass, University of Pennsylvania.

Sericite in foundry dust. Cornelius S. Hurlbut, Jr., Harvard University, and David S. Beyer, Liberty Mutual Insurance Co., Boston.

Quantitation of impinger dust samples by dark-field microscopy. Theodore Hatch, Harvard School of Public Health, and C. L. Pool, Rhode Island State Board of Health.

An automatic dust recorder. Willis G. Hazard and Philip Drinker, Harvard School of Public Health.

A death notice is given of Robert Prosser White, M.D., M.R.C.S. The book reviews cover (1) *Chronic nephritis and lead poisoning*, by L. J. Jarvis Nye, pp. 138, Sydney, Australia, Angus & Robertson, Ltd., 1933; (2) *Industrial health service*, by Leverett Dale Bristol, pp. 170, Philadelphia: Lea & Febiger, 1933; (3) *The principles of heating and ventilation*, by H. M. Vernon, pp. 232, London: Edward Arnold and Co., 1934. The abstracts complete the issue, pp. 43-73, followed by an author index for the abstracts.

Incidence of Illness Among Male Industrial Employees in 1933 as Compared With Earlier Years—The frequency of cases of sickness causing absence from work for more than one week among a group of 152,203 male industrial employees was lower in 1933 than in any other year since 1921 when the record was started. Compared with 1932 the decrease in sickness incidence was substantial. This result is somewhat surprising since the 1932 rates were below the average for the 5 preceding years.

The group under consideration is composed of male employees of 38 industrial firms most of which are located in the North Central, North Atlantic, and New England states, but a number of employees of these companies are

scattered in almost all parts of the country. The records on which the present report is based are those of sick-benefit organizations maintained either by the company or by its employees or coöperatively by both.

It is possible, of course, that the sickness rates might be higher if unemployed persons were included, but this consideration does not invalidate the year-to-year comparisons of sickness frequency among men working on a full-time or part-time basis. To some extent the decrease may be due to selection, *i.e.*, workmen on the payrolls now may be somewhat healthier as a group than those employed in 1928 and 1929 when the demand for labor was greater. Selection, however, does not appear to be the all-important factor. (Several tables show the frequency of disability by causes.)—Dean K. Brundage, U. S. Public Health Service, Release B-455 (received 5-7-34), 8 pp. mimeo.

Compensation for Occupational Diseases in Czechoslovakia—In 1933 the Bohemian Workers' Insurance Institute at Prague awarded compensation in 114 cases of occupational disease, distributed as follows:

Silicosis, 53 cases (6 fatal); glassworkers' cataract, 22 cases; lead poisoning, 18 cases; miners' pulmonary cancer (radium), 12 cases; eczema and nystagmus, 2 cases each; poisoning by mercury, aniline, carbon bisulphide and chlorine, and "muscle disease," 1 case each.—*Indust. & Labour Inf.*, 49, 11:359 (Mar. 12), 1934.

A Spanish Association for Industrial Medicine—A Spanish Association for Industrial Medicine was officially founded on January 17, 1934.

The Managing Committee of the Association includes Dr. Oller of Madrid as Chairman, Dr. Garcia Tornel of Barcelona as Vice-Chairman, and Dr. Polo of Madrid as Secretary. The As-

sociation is limited to 40 members, excluding corresponding members and honorary members.

The headquarters of the Association are in Madrid.—*Indust. & Labour Inf.*, 49, 11:359 (Mar. 12), 1934.

Occupational Diseases in Germany—The reports of the German industrial trade guilds contain information relating to compensation accorded for occupational diseases in the years 1929–1932:

Year	Cases Notified	Cases Compensated
1929	22,258	1,924
1930	15,006	3,255
1931	9,681	2,290
1932	6,493	1,711

In general, the number of cases of occupational diseases has thus decreased. This is attributed partly to the decline, owing to the depression, in the number of persons employed. It should be noted that, though the number of cases notified has fallen regularly, the same is not true of the number of cases compensated. Another table classifies the cases by industries. As a rule, silicosis was the chief affliction notified and compensated in each of the last 2 years, followed by lead poisoning.—*Indust. & Labour Inf.*, 49, 3:83 (Jan. 15), 1934.

Protection of Japanese Workers—A brief synopsis is given of (a) the anti-tuberculosis campaign in factories by the Bureau of Social Affairs, and (b) the preparation of a new bill for the protection of workers against white lead so as to comply more nearly with the Draft Convention, adopted by International Labour Conference in 1921.—*Indust. & Labour Inf.*, 49, 9:292 (Feb. 26), 1934.

Lead Poisoning in Australia—The problem of occupational lead poisoning is at present attracting much attention from Australian experts. In

Queensland, from July, 1931, to May, 1933, inclusive, 189 workers were admitted to hospitals. The question of occupational lead poisoning was also discussed at a meeting of the New South Wales branch of the British Medical Association on October 26, 1933, at which two papers were read dealing with the advanced diagnosis of lead poisoning and with the blood symptoms of such poisoning (*Med. J. of Australia*, December 16, 1933). The medical press observes that it is astonishing that such a state of things as that discovered at Mount Isa, in Queensland, should occur in the present state of our knowledge of this disease.—*Indust. & Labour Inf.*, 49, 9:293 (Feb. 26), 1934.

A Clinical Investigation of the Symptoms of Duco-Lacquer Poisoning—The admission to hospital, in the autumn of 1933, of a 20-year old painter's apprentice suffering from psychic ailments including depression, led to inquiries into the conditions under which he had been working.

It transpired that while at work with duco-lacquer, sprayed on to various surfaces by a compressed air apparatus, he had felt drunk and then had suffered from headache and a sense of heaviness with irritability. This case led the authors to investigate duco-lacquer work in Copenhagen. Of the approximately 200 persons thus employed in motor-car factories, etc., 73 were examined. A set of questions was drawn up, and the answers of the workers were noted with the following positive results: Drowsiness, 54; lassitude, 63; giddiness, 42; feeling drunk, 33; anorexia, 19; nausea, 13; vomiting, 11; pain in the heart region, 18; sore throat, 55; sore nose, 50; sore eyes, 42; salivation, 21; irritability, 47; disinclination for work, 42. In 36 cases these symptoms disappeared after a short holiday. The 15 workshops in-

spected could be classed in three groups according to the measures taken to protect the workers. Several of the workshops had provided masks of various designs, but nowhere were they found in use.

After discussing the various precautions against duco-lacquer poisoning, such as artificial ventilation with specially designed apparatus, the authors mention as the last, but perhaps most important, factor—that of the solvent of the lacquer. They believe that if all the solvents on the market were to be systematically analyzed and the most dangerous eliminated, a considerable reduction could undoubtedly be effected in the manifestations of duco-lacquer poisoning. The number of these solvents is legion.—M. Ellerman and J. Jakobsen, *Hospitalstidende*, 76:1213-21, 1933; *Bull. Hyg.*, 9, 4:235 (Apr.), 1934.

The Diagnosis of Lead Poisoning—The pharmacologist, Prof. Dr. Behrens, who has for years studied questions pertaining to lead, spoke recently before the Berlin Medical Society.

By the use of radioactive lead isotopes, with which he poisoned mice, he was able to establish that, contrary to other older views, lead poisoning constitutes a genuine cumulative disease resulting from a difference between the intake and the excretion of the poison. Lead accumulates chiefly in the liver and kidney, and secondarily in the bones. In the blood there is an adsorption by the red corpuscles. In the bones it is significant that the storage occurs chiefly in the subepiphyseal areas and under the periosteum. By the use of the radioactive lead the demonstration is simple, as the lead produces light spots on a photographic plate. It was possible in this manner to demonstrate that the lead undergoes

a rapid resorption and a slow excretion in the animal, and that it is a highly cumulative poison. But, when large quantities are ingested, a considerable portion is not resorbed by the intestine but is eliminated with the feces. The elimination of the stored portions takes place slowly; namely, along with the bile into the intestine and by way of the kidney. The elimination occurs in the form of lead sulphate, which is soluble with difficulty.

Behrens discussed the methods for the demonstration of small quantities of lead. He has adopted the method of H. Fischer, which, by means of a dye (diphenylthiocarbazone), demonstrates colorimetrically lead in quantities as low as thousandths of a milligram. Behrens emphasized that researches must be instituted to discover where the borderline between the normal and the pathologic secretion of lead lies. Until that has been done, it will be impossible to render an expert opinion in questions concerning the degree of disability or amount of compensation.—Berlin Letter, *J.A.M.A.*, 102, 19:1626 (May 12), 1934.

Federal and State Penal Institutions—A supplement accompanying the above issue of *Industry Report* tabulates the information obtained concerning prisoner employees in various federal and state penal institutions. The material concerns particularly the types and locations of such institutions, normal capacity, sources and reasons for confinement, number of employees, number of guards and other employees killed, cases of tuberculosis developed by employees, the prison population as of 7-1-28 and 7-1-33, with a column of comments referring principally to accidents, killings and population. Institutions comprising juvenile training schools and those for women are included.—Edited by N. W. Pettys.

EDUCATION AND PUBLICITY*

To the Health Officer or Other Chief Executive:

That your department or your association may benefit more fully from the Pasadena meeting we invite your consideration of the following:

- 1—That you assign one or more of your staff to attend and to report on sessions of the Public Health Education Section.
- 2—That you assign one or more of your staff to examine and study much of the material at Education and Publicity Headquarters.
- 3—That this year you give special thought to the practicability of sending to Pasadena staff members who usually do not get to attend A.P.H.A. meetings.
- 4—That before your delegation starts for Pasadena there will be made up a list of questions to be answered and matters on which information is to be gathered by one or more of your staff.

Bigger and Better Space at Pasadena—More space than ever before and better located space will be available for health education and publicity headquarters at Pasadena. There will be an ample collection of portfolio display material from the Russell Sage Foundation and the Social Work Publicity Council. Among this will be some special collections revised or made up for the occasion.

We will share with Scientific Exhibits the collection of material brought by Dr. W. W. Peter from his trip among health workers in other countries. And across the aisle will be the Scientific Exhibits, many of which will be of particular interest to those concerned with health education.

Please Write Before You Pack—As soon as you decide what you will send to Education and Publicity Headquarters at Pasadena please explain

what you have in mind, addressing Evart G. Routzahn, chairman, Education and Publicity Headquarters, 130 East 22d St., New York, N. Y. You will receive shipping and other information.

Very Much Wanted for Pasadena—Because we will have space, and because we will have the audience, we hope for unusual contributions of exhibit material from health agencies.

From nationals we would like portfolio or scrapbook collections of their health education material and their handbooks, publication lists, and other aids to local health education and publicity workers.

From commercial sources and special services similar portfolio or scrapbook collections of material available free or otherwise throughout either the United States or Canada.

From state and local departments and associations we would like to select material and would appreciate information at the earliest possible moment about projects in health education, radio

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

programs, and other types of material which might be collected in a portfolio or other form convenient for examination by conference delegates.

Or, have you devices or display material or projection material? Probably we could arrange for showing 16mm movies, if any are offered.

In all cases such material should be sent direct to Pasadena. Do not send it to New York. But please write in advance so that we may know exactly what is being sent, and may forward shipping instructions.

A copy of a memorandum on making up portfolio collections of samples will be sent free upon request to Evart G. Routzahn, Russell Sage Foundation, 130 East 22d St., New York, N. Y.

In all cases when copies are available—free, or for a price, or for a definite amount of postage—please give specific information to that effect.

It will add to the interest and value of your material to include notations as to use made of what you send, number issued, costs, and so on.

All material should be sent with charges fully prepaid.

If you wish your material returned please be sure to make specific arrangements for repacking and return shipping.

"Free" at Pasadena—A special table at Education and Publicity Headquarters will be provided for free material for distribution. Thus you may share with others any surplus of printed matter or other material.

Please write for shipping instructions.

Bring Plenty of Address Cards—If you don't fail us and do attend the demonstration session led by Mr. Routzahn, and get into any of the conference hours and study the displays at Education-Publicity Headquarters, you will wish to have a lot of your address cards. You may substitute 3 by 5 inch

slips on which has been typewritten your name, title, department or health agency name, and address in full.

Various publications, items of information, and samples will be sent to you free of expense by simply noting on a card or slip a number or word you will hear in one of the conference hours, or you will find marked in one of the display portfolios. Wonderful!

Conference and Consultation—At practically all hours when Public Health Education Section is not in session at Pasadena there will be consultation and question service at Education and Publicity Headquarters. The editor of this department will be assisted by officers and members of the Section. *We want to learn about your successes and your problems.*

Special group conferences will be held daily on such subjects as

Homemade lantern slides and their use; practical projection possibilities for promotion and propaganda; how to lay out a year's program; making use of the Women's Crusade next fall; window displays and other exhibits; radio broadcasts; amateur movies; better and cheaper house organs.

For Business and Pleasure—*All those who have decided that they will join the Public Health Education Section* are invited to join with members and fellows of the Section in the annual business dinner.

It never is a melancholy affair and it is the one period of the year when any considerable group may get together for acquaintanceship and for conference on the advancement of health education throughout the continent.

If you happen to be one of the unfortunates who will not get to Pasadena please write us a letter or send a telegram to be read at the business dinner. Address to an officer of the Section or to the editor of this department. Especially would we like to hear from our fellow-members in Europe,

Asia, Africa, Australia, and south of the Rio Grande River.

In the *Journal* for May, 1934—References to health education appeared in several articles in the May, 1934, issue of *American Journal of Public Health*. The following are of interest: "Public Health With the Civilian Conservation Corps Work Camps." Editorial.

"Medical Sensationalism in the Press." Editorial.

"Health and Beauty" (page 484).

"Annual Conference of the New England Health Education Association" (page 448).

A Correction of the Year Book—Please note correction of Committee on Health Education Institutes on page 30, *American Public Health Association Year Book*, 1933-1934. Cross off the name of Evert G. Routzahn who happens not to be a member of the committee.

Motion Picture on Typhoid Fever—If you know of a 35mm or 16mm motion picture for sale, rent, or loan, please tell Dr. Frank J. Jirka, State Director of Public Health, Springfield, Ill.

Where to Study Health Education?—A hopeful health worker has written to Dr. H. E. Kleinschmidt, National Tuberculosis Association, 50 W. 50th St., New York, N. Y., asking where to find a summer school course in public health education.

Please report any course of any type to Dr. Kleinschmidt who will inform this inquirer, and will then let us pass the information on to *Journal* readers.

Where will health education courses be given next fall or winter?

Which of the professional public

health schools give courses, or part courses?

Does any state offer correspondence or other extension courses?

Please tell us—for the readers of the *Journal*.

And who would care for a correspondence course, and how much would you be willing to pay for it?

SAFETY

"The Dangerous Age" (fatal-accident record of young drivers) and "There's No Place Like Home—For Accidents" offer usable material. *Travelers Standard*, Hartford, Conn. April, 1934. *Free*.

The 1934 wall calendar issued by the Utica, N. Y., Mutual Insurance Company, is the latest of a series, each page dealing with a simple, commonplace "accident." The sketch on each sheet and the accompanying conversational caption tells the story in a flash.

"The Great American Gamble" is the latest of the series of large-page pamphlets making use of picture diagrams and other graphic devices to emphasize automobile hazards and the high death and accident rates due to reckless or unintelligent driving. Earlier issues: "They Call Us Civilized"; "Tremendous Trifles"; "Worse than War" (out of print). Copies *free* upon request. *Travelers Insurance Co.*, Hartford, Conn.

For the reduction of street accidents the grand prize has been awarded to Evanston, Ill., by National Safety Council. The winners by population groups were: Milwaukee, Providence, Grand Rapids, Evanston, Fond du Lac, and La Grange. Details as to what the cities did to make the awards possible appear in *Public Safety*, 20 N. Wacker Drive, Chicago, Ill. April, 1934. *Free*.

BOOKS AND REPORTS

Manual of Veterinary Bacteriology
—By *Raymond L. Kelser, D.V.M., A.M., Ph.D.* Baltimore: *Williams & Wilkins*, 1933. Price, \$5.50.

Since textbooks on this particular subject are few, the first edition, published June, 1927, was received with much interest and appreciation by the veterinary profession and by the medical profession as well because of the inter-transmissibility of some animal and human diseases.

In this second edition, the author has improved the *Manual* very much by the addition of new material. A chapter has been included on the "Outstanding Phases of Bacterial Variation" as at present conceived, written by Major James S. Simmons, Medical Corps, U. S. Army.

In the nomenclature and classification of bacteria, the author has followed Bergey and the committee assisting him.

Another point that adds interest is the introduction to the section on protozoa, by Charles F. Craig, Director of the Department of Tropical Medicine, Tulane University Medical School. This is splendidly written and aids one in making use of the following chapters on this subject.

The title would indicate that it is a book on bacteriology but it is much more than that. It includes briefly not only all phases of the bacteriology of diseases in animals but also other disease producing organisms of animals, such as fungi, protozoa and viruses, and associated subjects, as serology, hematology, preparation of veterinary biological products and the bacteriological examination of milk and water.

For those not already acquainted with bacteriological methods and common forms of disease producing organisms, Part I, Bacteria, Their Morphology, Physiology and Classification, and Part II, Bacteriological Methods, will be of much interest. Part III, Infection and Immunity, is well written.

The printing and make-up of the book are excellent. A few typographical errors have been noted, only one of which needs mention. In the index, page 552, "Yersen" should be "Yersin."

The second edition of this *Manual of Veterinary Bacteriology* is a valuable addition to veterinary literature and the author is to be congratulated for its careful, concise and accurate preparation.

A. J. DURANT

Bergey's Manual of Determinative Bacteriology—By *David H. Bergey*. Baltimore: *Williams & Wilkins*, 1934. 664 pp. Price, \$6.00.

The first edition of this book appeared in August, 1923, since which three others have followed. The previous editions have been reviewed and criticised by various journals.

The changes in the present volume are best described in the preface signed by the Committee on Manual. Two new genera have been recognized in Tribe Bacteriae, namely Genus *Brucella* and Genus *Listerella*. Genus *Pfeifferella* has been combined with Genus *Actinobacillus*. The descriptions of *Leuconostoc*, *Propionibacterium*, *Bacterioides*, and Order *Myxobacteriales* have been amplified. Descriptions of some 50 new species have been included, while several organisms have been

omitted as distinct species, and the names recognized as synonyms for other species.

The committee points out that much intensive study is still needed to supply information on other genera, especially those in which a large number of species are included, and considers it probable that certain organisms now recognized under distinct names are really the same as other species.

The book is well printed and is remarkably free from typographical errors. It represents a vast amount of careful study and compilation.

MAZÏCK P. RAVENEL

Chinese Medicine—By William R. Morse, M.D., LL.D., F.A.C.S. New York: Hoeber, 1934. Price, \$1.50.

This is one of the series of handbooks under the general title "Clio Medica," edited by E. B. Krumbhaar, which aim to present in a concise and readable form special phases of medical history that underlie modern medical science.

The theme of this interesting little book is that the principles and practices of Chinese medicine are based upon the Chinese theory of cosmogony, a branch of metaphysics that deals with the character of the universe as an orderly system or cosmos. Chinese cosmogony is in turn based upon a sexual dualism, the theories of the *Yang* and the *Yin*, the male and female. The author quotes Halde as saying that "*Yang* is the principle of heat and dryness, *Yin*, the principle of cold and humidity. The normal state, that of perfect health, cannot exist save as those two principles exist in perfect equilibrium."

In his preface the author states that Chinese "medical literature is large and of considerable historical value"; furthermore, that in China today "the whole history of medicine is on view," making it "the most wonderful oppor-

tunity for scientific research that can be found in the world," for side by side with modern methods introduced and maintained by medical missionaries and now reinforced by the funds and efforts of many native and foreign institutions, the practices of mythical, legendary, prehistoric, ancient, medieval and historical medicine are at this very moment being used.

The opening chapter on Chinese Natural Philosophy, points out that Chinese legendary accounts of medical practices date back some 3,000 years B.C., but that there are definite evidences of well developed medical practices at least 1,000 years B.C.; furthermore, that Chinese medicine reached its zenith, first, during the Han Dynasty, about 170 A.D., and again in the Sung Dynasty (960-1279 A.D.) during which valuable medical discoveries were made. Although Chinese medicine, founded upon a peculiar theory of cosmogony, contained some deep truths, yet "in actual practice their therapeutic procedures have become a pot-pourri of facts, fancies, and fatalism. At the present time the majority, if not all of their healing practices consist of a weird medley of philosophy, religion, superstition, magic, alchemy, astrology, *feng shui*, divination, sorcery, demonology and quackery." In fact, since the earliest time, "astrology has been considered the right eye and alchemy the left eye of medicine." Alchemy is said to have "originated in China and reached Alexandria in the third to fifth century A.D. But Chinese alchemy had as its goal both long life and immortality. It aimed to transform inanimate things into 'spiritual essences.'" Thus Taoism and alchemy came to mean much the same thing, for the "Taoists were said to have discovered an *elixir vitae*." It is of interest to note that the Chinese characters for alchemy, literally translated, mean "the golden pill of immortality."

The Chinese physician of the old school is steeped in the tenets and theories of alchemy. He strives to attain for his patients long life and immortality. In addition to much "medicine," he generally employs two very practical methods, first, a comprehensive regimen of mental and physical discipline; second, a regulated and selected diet of articles containing vital essence or force.

Since the Chinese practice of medicine appeals largely to the emotions, and since "fear of the unknown, unseen, multitudinous spirits predominates in Chinese religion, ethics and medicine," it was only natural for the people to create their own gods of medicine which are about as numerous as are the diseases of mankind. These gods have different ranks depending upon their relative importance. Among the few of the highest dignity are two who were celebrated physicians during the Han Dynasty. One of them Pien Ch'iao, famous as an internist, is renowned as the first to use a general anesthetic. The other, Hua T'o, the God of Surgery, whose birthday is nationally recognized, performed many major operations on the brain, abdomen and other parts.

The keynote of diagnosis in Chinese medicine is the palpation of the pulse, but the better physicians also employ other important procedures such as a scrutinizing personal and family history, a careful inspection of the patient, and listening (not auscultation) to the quality and character of the patient's voice and breathing. But of all these, palpation of the pulse is the most important. In fact, "the general consensus of opinion among the Chinese today is that all a doctor needs to recognize any disease is to feel the pulse." Fifty-one chief types of pulse are classified, of which 27 indicate a fatal ending to disease. Although the Chinese physician, like the rest of his countrymen, possesses the sense of

touch to a remarkable degree, such diagnostic methods "border on the ridiculous and possibly cross the line into absurdity."

The materia medica of China is probably more extensive than that of any other country. The Chinese physician believes that "every substance ingested into the body liberates either *Yang* or *Yin* spirit or force. If rightly chosen, healing results; if wrongly, disease occurs." The key to treatment is the production or depletion of *Yang* or *Yin* in the body through the action of suitable remedies which establish an equilibrium in the flow of these cosmic forces. A catalog of the great majority of these Chinese medicines reminds one of the list of remedies suggested by the third witch in Shakespeare's "Hamlet." The author states that "there is a large mass of useless, objectionable and nauseating remedies in their pharmacopeia, but there are many that are very useful, and moreover have been used for centuries for the same diseases and in somewhat similar manner as they have been and are used in the West, e.g., mercury, iron, arsenic, rhubarb, ma huang (ephedrine), camphor, aconite, iodine, seaweed, kaolin, arrow-root, castor oil, etc., etc."

The short chapters on Chinese anatomy and physiology show that although a few facts were discovered and accepted, these fundamental branches of medicine were to the Chinese physician almost "pure phantasmagoria."

The operation of acupuncture, a strictly Chinese procedure, consists in the introduction of hot or cold metal needles, 3 to 24 cm. long, into the living human body as remedial agents, "the object being to penetrate at certain definite points one or more of 12 hypothetical, invisible, undissectable channels, which, according to theory, contain the vital *Yang* and *Yin*," the male and female creative and destructive essences that exactly counterbalance

each other in all nature. Acupuncture aims to reestablish the harmony and proper balance of these essences in those parts of the body affected by disease.

"Chinese medicine at its best is vitalistic; ours is materialistic. Past masters in sophisticated adaptations, the Chinese have a system that is not elastic or adaptable to newer circumstances. Fixed in the thralldom of fate, the exercise of free will is well nigh impossible. Chinese culture and intelligence are not inferior, but China is stagnant and static, while the West is progressive and dynamic. The West investigates and attempts to control nature's laws to human needs, while China's theory premises that what has begun must continue and man must adapt himself to nature."

With a fanatical reverence for the past the Chinese "closed their minds to scientific advancement in medicine soon after the preliminary stages were passed. Superstitions and bizarre medical practices by individuals and groups, secular and religious, occur in the West. The difference is, China is swamped in superstition while the West is emerging from it."

There being no provincial or municipal regulations for practitioners, the number of those who call themselves doctors are legion. "Probably 80 per cent of the medical practices in China are carried out by charlatans." Since this book was printed, the National Government of China has promulgated a decree that all physicians, both native and foreign, will have to undergo an examination in order to procure a license to practise.

The author designates his book as an outline of the vast subject of Chinese medicine. It is an outline but vastly more; it is an encyclopedia of historic facts which are so pleasingly assembled that the book gives the effect of a delightful narrative. In addition his many quotations from Chinese philosophy and

medicine are such gems that the book deserves to be included in public and private libraries for its literary value alone.

HARVEY J. HOWARD

Nature, M.D. *Healing Forces of Heat, Light, Water, Electricity and Exercise—By Richard Kovacs, M.D. New York: Appleton, 1934. 173 pp. Price, \$2.00.*

This little treatise is the newest of the Appleton Popular Health Series. It is a handy, almost pocket size volume, written in the author's clear, concise, and easy to read style. As it is intended chiefly for lay use all technical terms are avoided as far as possible. Where they are used their meaning is explained in simple words, understandable even to those who know nothing of medicine or physics.

There are five main divisions or chapters, each dealing with one of nature's forces useful in maintaining health or in combating disease.

Heat, its application in the home by the simple common devices now available, and in the hospital by the newer more scientific methods is described.

Next, the use of *Water*, plain or mineralized, internally or externally, by baths of varying temperature; by sponges, packs, compresses; by whirlpool baths or Scotch douche; by enemas and colonic irrigations, is discussed and its rationale explained.

The use of *Light*, both natural and artificial, its benefits and dangers, and the precautions to be observed in its use are all well covered in chapter three.

Electricity in its most modern forms is described and a few of its chief indications given in chapter four.

The fifth chapter tells of *Massage, Exercise and Rest*, the why's and wherefore's of each in its proper place. A brief but sufficient index is included.

A book of this character has been

needed for some time to help in the debunking of the self-styled physical therapist and to offset the ballyhoo of the manufacturers of apparatus for lay use. It gives the public a simple yardstick by which to measure the value of physical agents. It is a splendid guide for the man-in-the-street on this subject.

H. M. HERRING

Miss Gay's Adventures in First Aid

—By *Margaret Daly Hopkins, R.N.*
New York: National Press Printing Company, Inc., 1933. 60 pp. Price, \$.15.

This small book dramatizes, in an interesting way, first aid treatment, particularly for babies: for choking from swallowing small objects; for eye injuries resulting from small objects getting into them, and for the removal of such objects; for the removal of small objects from the nose; and for ear treatment to dislodge small objects or to care for other emergency treatment.

It emphasizes the need of skilled medical treatment for these difficulties, while explaining carefully what should be done in emergencies.

CHARLES H. KEENE

Survey of Public Health Nursing—

By the N.O.P.H.N. New York: The Commonwealth Fund, 1934. 250 pp. Price, \$2.00.

There are 5,000 organizations in this country giving public health nursing service and nearly 20,000 public health nurses engaged in various phases of the program. Livingston Farrand says in the foreword of this volume that public health nursing has proved its value in the public health program, and the object of the present survey is to increase its effectiveness.

It is interesting to see that two official organizations, boards of health, and school boards, and one unofficial one, public health nursing associations, employ the bulk of public health nurses.

One waxes more curious as he reads on to see how the quality of public health nursing sponsored by these three organizations differs or compares.

Already at the Biennial Convention in Washington the school nursing section of the N.O.P.H.N. showed unusual signs of activity at the report that supervision of the health of the school child ranks poorest in quality of all activities of the public health nurse as shown in this study. All of us public health nurses were jolted out of our complacency to learn that under the limelight our teaching ability is not up to par.

Here is a chance for us to stand off and view ourselves impersonally for the good of our souls. And others who read will see why they need to stand behind us all the more solidly to help us train ourselves so that our weaknesses will be ironed out and our strong points reinforced.

There are rifts in the clouds, too, for the official agencies for the study showed they actually were doing some types of nursing better than the private public health nursing organizations.

But we must not reveal the whole content of the *Survey*, for it should be widely read and studied for far reaching improvements in our profession are likely to come because of it.

EVA F. MACDOUGALL

Cholera. A Manual for the Medical Profession in China—By *Wu Lien-Teh, Director, National Quarantine Service, J. W. H. Chun, Senior Quarantine Officer, National Quarantine Service, R. Pollitzer, Microbiologist, National Quarantine Service, and C. Y. Wu, Senior Quarantine Officer, National Quarantine Service. Shanghai, China: National Quarantine Service, 1934. Price, Cloth, \$3.00; Paper, \$2.50—post free.*

This most useful book is divided into four parts: Part I, Historical, Geo-

graphical and Epidemiological Aspects, by Wu Lien-Teh; Part II, Laboratory Aspects, by R. Pollitzer; Part III, Clinical Aspects, by J. W. H. Chun; and Part IV, Education and Propaganda, by C. Y. Wu. In addition, there is an appendix by C. Y. Wu on The Spread and Control of Sea-Borne Cholera.

As the title implies, this book has been written as a manual for the medical profession in China. It contains a large amount of useful information. The historical material by Dr. Wu is particularly interesting, but the other writers have given us excellent material describing the methods carried out in China against this disease which was only a short time ago a world menace.

A good index adds to the value of the volume. We must pay tribute to the activities of Dr. Wu, the Director of the National Quarantine Service, when we consider the number of excellent publications which have been pro-

duced during the past few years under exceptionally difficult circumstances.

The printing and binding of the book are excellent. The book can be recommended to all health officers, especially since we have become a world power and since China has been brought within days of our shores by fast steamship travel instead of weeks and months, as was the case only a few years ago.

MAZÛCK P. RAVENEL

Popular Health Science Talks—
Vol. X. Philadelphia: Philadelphia College of Pharmacy and Science, 1933. 307 pp. Price, \$1.00.

This latest volume of an excellent series is distinguished by a fine, brief history of the more spectacular advances in medical research. As in the preceding volumes, the other papers cover a wide range of subjects, all of which will appeal to the sanitarian whose interests reach beyond his own narrow field.

RAYMOND S. PATTERSON

BOOKS RECEIVED

A REVIEW OF NURSING, WITH OUTLINES OF ALL CURRICULUM SUBJECTS AND OBJECTIVE OF NEW-TYPE QUESTIONS. By Helen F. Hansen. Philadelphia: Saunders, 1934. 635 pp. Price, \$3.00.

DISEASES PECULIAR TO CIVILIZED MAN. By George Crile. New York: Macmillan, 1934. 427 pp. Price, \$5.00.

CHILD GUIDANCE CLINICS. A Quarter Century of Development. By George S. Stevenson and Geddes Smith. New York: Commonwealth Fund, 1934. 186 pp. Price, \$1.50.

MODERN DRUG ENCYCLOPEDIA AND THERAPEUTIC GUIDE. By Jacob Gutman. New York: Hoeber, 1934. 1393 pp. Price, \$7.50.

A STUDY OF SCHOOL HEALTH STANDARDS. By Anette M. Phelan. Published by the Author. 1934. 249 pp. Price, \$2.50.

THE SOCIAL ADJUSTMENT OF THE TUBERCU-

LOUS. By Beulah Weldon Burhoe. New York: National Tuberculosis Association, 1934. 55 pp. Price, \$.50.

THE MEASUREMENT OF SOCIAL STATUS BY THE USE OF THE SOCIAL STATUS SCALE, 1933. By F. Stuart Chapin. Minneapolis: University of Minnesota Press, 1934. 16 pp. Price, \$.25.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Diphtheria Continues Response to Preventive Measures—Diphtheria death rates in large cities continue to decline except in the South where prophylactic immunization has been neglected. As usual, most of the deaths were in children under 5 years.

ANON. Diphtheria Mortality in Large Cities of the United States in 1933. *J.A.M.A.* 102, 21:1758 (May 26), 1934.

More Credit for Public Health Administration—Typhoid fever mortality rate reduction continues. During 1934 the rate was 1.18, the lowest yet reported for the large cities of the country. This is less than half what it was only 7 years ago.

ANON. Typhoid in the Large Cities of the United States in 1933. *J.A.M.A.* 102, 20: 1677 (May 19), 1934.

Anti-Tuberculosis Measures Abroad—Five papers about tuberculosis in this British symposium discuss the disease as it affects young women, the relation of dental condition to the progress of tuberculosis, difficulties in early diagnosis, and the conduct of workshops for the tuberculous. Altogether a useful series of papers.

BENTLEY, F. J. *et al.* Pulmonary Tuberculosis in Young Women. *J. State Med.* 42, 5:249 (May), 1934.

Constipation—Constipation is due more than anything else to irregular toilet habits. After irritating cathartics are discontinued, regularity in eating, exercise, and toilet habits effectually prevents the condition.

BEAURY, A. G. The Treatment of Constipation. *New Eng. J. Med.* 210, 21:1116 (May 24), 1934.

Better Industrial Health—The frequency of sicknesses causing absence from work of more than a week was less in 1933 than in any year since 1921 when the sickness surveys among industrial employees were first started.

BRUNDAGE, D. K. Incidence of Illness Among Male Industrial Employees in 1933 as Compared with Earlier Years. *Pub. Health Rep.* 49, 21:615 (May 25), 1934.

Do We Require Too Much Reporting?—Notification is useless in the instances of measles, whooping cough, chicken pox, mumps and influenza, and of little use in scarlet fever and erysipelas. In a well vaccinated population, smallpox notification would be unnecessary. Only in the instances of diphtheria and intestinal infections is it of great value, for in sporadic cases of meningitis, poliomyelitis, encephalitis it cannot be said (by this British epidemiologist) to be of any great importance. Contact control is of value in smallpox, typhoid fever, cerebrospinal fever and tuberculosis; in others, it is useless.

CATTO, H. W. The Changing Outlook on the Control of Infectious Diseases. *J. Roy. San. Inst.* 54, 11:559 (May), 1934.

Heart Disease in Childhood—It is said that three-quarters of all cases of heart disease develop before the age of 10. The opportunity is great for the school physician to prevent heart disease by the discovery of early signs.

DEPORTE, J. V. Heart Disease Among Children of School Age. *New York State J. Med.* 34, 10:448 (May 15), 1934.

World Plans Against Cancer—European opinion on the needs for

special organization to further cancer treatment and prevention is summarized by this Swedish authority. He concludes that the best form of propaganda is to have a large number of cured cancer patients.

FORSSELL, G. The Campaign of Society against Cancer (and) Sweden's Anti-Cancer Campaign. *Am. J. Cancer*, 20, 4:848 (Apr.), 1934.

Some Anti-Hookworm Campaign Results—A large sample of the Mississippi population showed a hookworm infestation of 20 per cent as compared with 53 per cent in 1910. During these years, 200,000 people have had hookworm treatment, but despite some sanitary improvements, only one-tenth of the rural homes have adequate sewage disposal.

KELLER, A. E., *et al.* An Investigation of the Incidence and Intensity of Infestation of Hookworm in Mississippi. *Am. J. Hyg.* 19, 3:629 (May), 1934.

Health Insurance Urged Again—What we now spend for that variety of services we think of as medical care would provide better medical services for all below the \$5,000 income level, and better remuneration for the servants if we adopted a perfectly practical scheme of social medicine, says this writer.

KINGSBURY, J. A. Mutualizing Medical Costs. *Survey Graphic*, 23, 6:285 (June), 1934.

Social Medicine for Alberta—The proposal for the Canadian province suggests a per capita fee of \$2.01 per month for employees, and \$2.82 for

others who are heads of families, the fund to provide medical, dental, nursing and hospital services for everyone.

McGUGAN, A. C. Alberta State Health Insurance Report. *Canad. Pub. Health J.* 25, 4:155 (Apr.), 1934.

All About Silicosis—Causes, symptoms and prevention of silicosis are presented briefly and clearly in this excellent review of the subject.

SAYERS, R. R. Silicosis. *Pub. Health Rep.* 49, 20:595 (May 18), 1934.

The Vitamins Fail in Their Duties—In a British community in which the diets were grossly deficient in vitamins A and D, concentrates were given to controlled groups. The rate of growth in the treated group was only slightly better than the control and there was no indication of any effect upon resistance to infection.

SUTHERLAND, R. Vitamins A and D: Their Relation to Growth and Resistance to Disease. *Brit. M. J.* 3826:791 (May 5), 1934.

Fomites and Disease Spread—Epidemiologic study of a British epidemic of combined diphtheria and scarlet fever convinces the author that second-hand clothing sales had no effect, no milk-borne infection was discovered, but that many cases came from overcrowded, insanitary slum dwellings. Just how much of a factor the insanitary conditions constitute the authors do not reveal. The question of fleeting contacts is raised but not answered.

WILSON, J. G. The Spread of Infectious Diseases. *J. Roy. San. Inst.* 54, 11:553 (May), 1934.

PRELIMINARY PROGRAM OF THE SIXTY-THIRD ANNUAL MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

PASADENA, CALIF., SEPTEMBER 3-6, 1934

THE Annual Meeting Program Committee presents the preliminary program of the scientific sessions of the Sixty-third Annual Meeting of the American Public Health Association and Information concerning meetings of related organizations.

The program of the Third Institute on Health Education to be held August 31, September 1, 2 and 3 will be found on page 796.

Since the following program cannot be considered definite in every respect now, delegates are urged to consult the Final Program, available at the Registration Desk in the Maryland Hotel at the time of the meeting.

Monday, 9:30 A.M.

HEALTH OFFICERS

First Session—Main Hall—Auditorium

SERVING THE PUBLIC FOR HEALTH

Speakers: HENRY F. VAUGHAN, DR.P.H., Health Commissioner, Detroit, Mich., and Member of Board, W. K. Kellogg Foundation, Battle Creek, Mich., and J. L. POMEROY, M.D., Health Officer, Los Angeles County Department of Health, Los Angeles, Calif.

Discussion. WALTER L. BIERPING, M.D., State Health Commissioner, Des Moines, Ia., JOHN J. SIPPY, M.D., District Health Officer, San Joaquin Local Health District, Stockton, Calif., and WARREN F. DRAPER, M.D., State Health Commissioner, Richmond, Va.

PUBLIC HEALTH ENGINEERING

First Session—Gold Room—Maryland Hotel

WATER SUPPLY AND TREATMENT

Pasadena's Water Supply and the Los Angeles Metropolitan Water District.
S. B. MORRIS, Chief Engineer, Water Department, Pasadena, Calif.

Chlorination of the Los Angeles Water Supply. Speaker to be selected.

Contamination of Water Supplies with Oil Well Brines. EARNEST BOYCE, Director, Division of Sanitation, State Board of Health, Lawrence, Kans.

Sanitation of Mountain Playgrounds with Respect to Contamination of Streams.
C. G. GUTTERIE, Chief Engineer, State Department of Health, Berkeley, Calif.

Reclaiming Acid Streams. Speaker to be selected.

Monday, 9:30 A.M.

FOOD AND NUTRITION

First Session—Main Dining Room—Maryland Hotel

Effect of Economic Changes on the Nutrition of a People. ALONZO E. TAYLOR, Director, Food Research Institute, Stanford University, Calif.

The Nutritional Aspects of Milk Pasteurization. Professor E. V. McCOLLUM, Johns Hopkins University, Baltimore, Md.

The Public Health Aspect of the Relation of Diet to Dental Health. NINA SIMMONDS, PH.D., University of California, San Francisco, Calif.

Discussion. GUY S. MILLBERRY, D.D.S., Dean, College of Dentistry, University of California, San Francisco, Calif.

Fluorine and Its Relation to Public Health. FLOYD DEEDS, PH.D., Bureau of Chemistry and Soils, U. S. Department of Agriculture, San Francisco, Calif.

Report of the Committee on Nutritional Problems. *Chairman,* D. BREESE JONES, PH.D., Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

The Nutritive Value of Dried Fruits. AGNES FAY MORGAN, PH.D., Department of Household Science, University of California, Berkeley, Calif.

Use of Dinitrophenol in Nutritional Disorders. MAURICE L. TAINTER, Associate Professor of Pharmacology, and WINDSOR C. CUTTING, Resident in Medicine, Stanford University School of Medicine, San Francisco, Calif.

Discussion. P. J. HANZLIK, M.D., Department of Pharmacology, Stanford University School of Medicine, San Francisco, Calif.

CHILD HYGIENE

First Session—Assembly Room—Auditorium

PROBLEMS OF THE SCHOOL CHILD

Report of School Health Studies. DONALD B. ARMSTRONG, M.D., Third Vice-President, Metropolitan Life Insurance Company, New York, N. Y.

Practical Application of Principles of School Health Research. HAROLD H. MITCHELL, M.D., School Health Service, Freeport, N. Y.

Discussion. ALVIN POWELL, M.D., Oakland, Calif.

Mental Hygiene as a School Problem. FORREST ANDERSON, M.D., Director, Los Angeles and Pasadena Child Guidance Clinic, Los Angeles, Calif.

Discussion. OLGA BRIDGMAN, M.D., Psychiatrist, University of California Medical School, San Francisco, Calif.

The Value of the Fluoroscope in Case Finding Among Children. HAROLD FELLOWS, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Discussion. MERLE PINDELL, M.D., Los Angeles County Health Department, Los Angeles, and ROBERT S. STONE, M.D., Associate Professor of Roentgenology, University of California Medical School, San Francisco, Calif.

Health Problems in Rural Schools. HELEN HEFFERNAN, Chief, Division of Elementary Education and Rural Schools, Sacramento, Calif.

Discussion.

Monday, 9:30 A.M.

**PUBLIC HEALTH NURSING SECTION AND AMERICAN
SOCIAL HYGIENE ASSOCIATION**

Joint Session—Ball Room—Huntington Hotel

**THE PART OF THE PUBLIC HEALTH NURSE IN THE
EPIDEMIOLOGY OF SYPHILIS**

Presiding: ELENORA THOMSON, Professor of Public Health Nursing, University of Oregon, Portland, Ore., and PEARL McIVER, R.N., *Chairman*, Public Health Nursing Section, U. S. Public Health Service, Washington, D. C.

When and How Is Syphilis Communicable and How Rendered Non-Infectious? WALTER CLARKE, M.D., American Social Hygiene Association, New York, N. Y.

What Powers and Responsibilities Have Health Authorities to Prevent the Spread of Syphilis? J. ROSSLYN EARP, M.D., Director, Bureau of Public Health, Department of Public Welfare, Santa Fe, N. Mex.

Case Finding and Case Holding Activities of Public Health Nurses in Relation to Syphilis. Problems and Experiences.

Maternity and Child Health Services. Speaker to be selected.

City Health Department Clinics. Speaker to be selected.

Generalized Public Health Nursing Service in Cities. NAOMI DEUTSCH, R.N., Director of Visiting Nurses, San Francisco, Calif.

General Public Health Nursing Services in Rural Areas. EDITH S. COUNTRYMAN, R.N., Director of Public Health Nursing, State Department of Health, Des Moines, Ia.

Questions and Discussion.

LABORATORY

First Session—Exhibition Hall—Auditorium

Address of the Chairman. ROBERT S. BREED, PH.D., Chief-in-Research, New York State Agricultural Experiment Station, Geneva, N. Y.

Section Business.

Report of the Coördinating Committee on Standard Methods. *Chairman,* A. PARKER HITCHENS, M.D., Major, Medical Corps, U. S. Army, Walter Reed Hospital, Army Medical Center, Washington, D. C.

Report of the Committee on Diagnostic Procedures and Reagents. *Chairman,* W. D. STOWALL, M.D., Director, State Laboratory of Hygiene, Madison, Wis.

Report of the Committee on Examination of Dairy and Food Products. *Chairman,* ROBERT S. BREED, PH.D., Chief-in-Research, New York State Agricultural Experiment Station, Geneva, N. Y.

Report of the Committee on Milk Pasteurization Studies. *Chairman,* ROBERT S. BREED, PH.D.

Report of the Committee on Advisability of Laboratory Examination of Food Handlers. *Chairman,* MINNA CROOKS YOUNG, Associate Director of Laboratories, State Department of Health, Lansing, Mich.

Monday, 9:30 A.M.

LABORATORY (Cont.)

First Session—Exhibition Hall—Auditorium

Report of the Committee on Water Pollution Studies. *Chairman*, JAMES A. NEWLANDS, Henry Souther Engineering Company, Hartford, Conn.

Report of the Committee on Swimming Pool and Bathing Place Waters. W. L. MALLMANN, PH.D., Department of Bacteriology and Hygiene, Michigan State College, East Lansing, Mich.

Report of the Committee on Section Representation on the Governing Council. *Chairman*, FRIEND LEE MICKLE, Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.

Monday, 12:30 P.M.

INDUSTRIAL HYGIENE

Luncheon Session—Grill Room—Maryland Hotel

Report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases. *Chairman*, HENRY H. KESSLER, M.D., Department of Labor, Newark, N. J.

Report of the Committee on Lead Poisoning. *Chairman*, ALBERT S. GRAY, M.D., State Department of Health, Hartford, Conn.

Report of the Committee on Industrial Fatigue. *Chairman*, FREDERICK B. FLINN, Columbia University, New York, N. Y.

The Industrial Hygiene Section, 1914–1934. EMERY R. HAYHURST, M.D., PH.D., Consulting Hygienist, Columbus, O.

PUBLIC HEALTH NURSING

Luncheon Session—Crystal Room—Huntington Hotel

Speaker to be selected.

Monday, 1:00–4:00 P.M.

PUBLIC HEALTH EDUCATION

First Session—Belvedere Gardens, East Side Health and Welfare Center,

Los Angeles County Health Department

A Demonstration of Health Education Methods.

Monday, 2:30 P.M.

LABORATORY

Second Session—Indiana Room—Auditorium

Presiding: MAZŸCK P. RAVENEL, M.D., *Vice-Chairman* of the Laboratory Section, University of Missouri, Columbia, Mo.

Approval of Laboratories for Surgical Pathology in New York State. A. B. WADSWORTH, M.D., and RUTH GILBERT, M.D., Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Relapsing Fever Problem of California. GEORGE E. COLEMAN, Research Associate in Medicine, The George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

Typhus Fever. JAMES G. MCALPINE, PH.D., Director of Laboratories, State Department of Health, Montgomery, Ala.

Rocky Mountain Spotted Fever: Results of Ten Years' Prophylactic Vaccination. R. R. PARKER, PH.D., Special Expert, Officer in Charge, U. S. Public Health Service, Hamilton, Mont.

The Weil-Felix Reaction in Rocky Mountain Spotted Fever and Its Relation to Certain Other Typhus-Like Diseases. GORDON E. DAVIS, SC.D., Bacteriologist, Spotted Fever Laboratory, U. S. Public Health Service, Hamilton, Mont.

Pleo-Antigenicity of Proteus X-19. HENRY WELCH, PH.D., Research Microbiologist, FRIEND LEE MICKLE, Director, and EARLE K. BORMAN, Assistant Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.

LABORATORY AND FOOD AND NUTRITION SECTIONS

Joint Session—Main Hall—Auditorium

Presiding: WALTER H. EDDY, PH.D., *Chairman*, Food and Nutrition Section, Teachers College, Columbia University, New York, N. Y., and ROBERT S. BREED, PH.D., *Chairman*, Laboratory Section, Chief-in-Research, New York State Agricultural Experiment Station, Geneva, N. Y.

Report of the Committee on Microbiological Methods of Food Examination. *Chairman*, LAWRENCE H. JAMES, PH.D., Food Research Division, Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

Processing Fruits and Vegetables in California. J. R. ESTY, PH.D., Director, Western Branch Laboratory, National Canners Association, San Francisco, Calif.

The Results of California's Dairy Control Set-Up. CHARLES U. DUCKWORTH, D.V.M., Assistant Director, Department of Agriculture, Sacramento, Calif.

Methods of Identifying Streptococci in Dairy Products. G. J. HUCKER, PH.D., and P. ARNE HANSEN, New York State Agricultural Experiment Station, Geneva, N. Y.

Mussel Poisoning. H. SOMMER, PH.D., and KARL F. MEYER, M.D., Professor of Bacteriology, The George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

Home Canning and Public Health. F. W. TANNLEP, PH.D., Department of Bacteriology, University of Illinois, Urbana, Ill.

Coli-Aerogenes in Wagon Milk, Raw and Pasteurized. VIVIENNE HUDSON, and H. W. HILL, M.D., D.P.H., Director, Provincial Board of Health Laboratories, Vancouver, B. C.

Monday, 2:30 P.M.

VITAL STATISTICS

First Session—Main Dining Room—Maryland Hotel

Section Business.

Residence Correction (Report of the Committee). *Chairman*, J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Traffic Accidents. H. L. BARLOW, Superintendent of Records and Identification, Department of Police, Los Angeles, Calif.

Trends in the Prevalence of Diphtheria. ESCHSCHOLTZIA L. LUCIA, PH.D., Assistant Professor of Biometry, Department of Hygiene, University of California, Berkeley, and HILDA F. WELKE, Statistician, Division of Vital Statistics, City and County Department of Public Health, San Francisco, Calif.

Variable Factors in Pernicious Anemia. L. R. GATES, D.P.H., Instructor in Hygiene and Public Health, and Sanitarian to Health Service, University of Michigan, Ann Arbor, Mich.

The Cause of Breast Cancer. EMIL BOGEN, M.D., Olive View Sanatorium, Olive View, Calif.

PUBLIC HEALTH ENGINEERING

Second Session—Exhibition Hall—Auditorium

High Temperature Short-Time Pasteurization of Milk. R. E. IRWIN, Milk Plant Engineer, State Department of Health, Harrisburg, Pa. (*Stereopticon Illustration.*)

Discussion. C. S. MUDGE, Associate Professor of Dairy Industry, University of California, College of Agriculture, Davis, Calif.

Relation of Retail Price of Milk to Production Costs. THOMAS PARRAN, JR., M.D., State Health Commissioner, Albany, N. Y.

Sanitary Works Made Beautiful. Speaker to be selected.

Aerial Nuisances and Oil Refineries. Speaker to be selected.

Sanitation in Large Irrigation Districts. Speaker to be selected.

EPIDEMIOLOGY

First Session—Assembly Room—Auditorium

Epidemiological Studies on Relapsing Fever in California. HARLIN L. WYNNS, M.D., Chief, Bureau of Epidemiology, and DOROTHY BECK, Junior Epidemiologist, State Department of Health, San Francisco, Calif. (*Stereopticon Illustration.*)

Some Notes on Typhoid Fever. EDWARD S. GODFREY, JR., M.D., Director, Local Health Administration, State Department of Health, Albany, N. Y. (*Stereopticon Illustration.*)

Observations on Unusual Outbreaks of Epidemic Disease in Rural Areas in Iowa. CARL F. JORDAN, M.D., Epidemiologist, State Department of Health, Des Moines, Ia.

Monday, 2:30 P.M.

EPIDEMIOLOGY (Cont.)

First Session—Assembly Room—Auditorium

Sources and Modes of Infection in Two Family Epidemics of Syphilis. A. L. GRAY, M.D., Epidemiologist, State Board of Health, Jackson, and W. H. CLEVELAND, M.D., Health Officer, Lee County, Miss. (*Stereopticon Illustration.*)

Some Factors in the Epidemiology of Malaria. HENRY HANSON, M.D., State Health Officer, MARK F. BOYD, M.D., Rockefeller Foundation, and T. H. D. GRIFFITHS, U. S. Public Health Service, Jacksonville, Fla.

Monday, 6:30 P.M.

PUBLIC HEALTH EDUCATION

Dinner Session—Grill Room—Maryland Hotel

Closed Session—for Fellows and Members of the Section.

Monday, 8:00 P.M.

FIRST GENERAL SESSION

Main Hall—Auditorium

Invocation. DEAN HARRY BEAL, St. Paul's Cathedral, Los Angeles, Calif.

Addresses of Welcome:

J. D. DUNSHEE, M.D., Chairman of the Pasadena Local Committee.

WILTON L. HALVERSON, M.D., Health Officer, Pasadena, Calif.

E. O. NAY, Chairman, Board of City Directors.

LOUIS L. HENNINGER, M.D., President, Pasadena Branch, Los Angeles County Medical Association.

MRS. PHILIP SCHUYLER DOANE, President, Women's Auxiliary, California State Medical Association.

Address of the President of the American Public Health Association. HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Announcement of Awards.

Tuesday, 9:30 A.M.

INDUSTRIAL HYGIENE

First Session—Gold Room—Maryland Hotel

Address of the Chairman of the Section. R. R. SAYERS, M.D., Chief Surgeon, U. S. Bureau of Mines, Washington, D. C.

Health Hazards in the Oil Industry. R. A. JEWETT, M.D., Medical Director, General Petroleum Corporation of California, Los Angeles, Calif.

Lead Poisoning Statistics for 1933. FREDERICK L. HOFFMAN, LL.D., Consulting Statistician, Prudential Life Insurance Company of America, Philadelphia, Pa.

Tuesday, 9:30 A.M.

HEALTH OFFICERS

Second Session—Dining Room—Maryland Hotel

No Title. ALBERT RAY SOUTHWOOD, M.D., Chairman, Central Board of Health, and Head, Department of Public Health of South Australia, Adelaide, S. Australia.

The Changes That Have Occurred in Twelve of the Most Important Diseases Since 1900. LOUIS I. DUBLIN, PH.D., Third Vice-President and Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Programs and Plans of the Tennessee Valley Authority Medical and Health Section. E. L. BISHOP, M.D., State Commissioner of Public Health, Nashville, Tenn.

Trends in Public Health Nursing. PEARL MCIVER, R.N., U. S. Public Health Service, Washington, D. C.

Health Insurance Legislation. Spcaker to be selected.

European Health Officers. W. W. PETER, M.D., White Plains, N. Y.

The Plague Situation in California. W. H. KELLOGG, M.D., Chief, Bureau of Laboratories, State Department of Health, Berkeley, Calif.

Rural Health Conservation Contest. CARL E. BUCK, DR.P.H., Field Director, American Public Health Association, New York, N. Y.

LABORATORY AND PUBLIC HEALTH ENGINEERING SECTIONS

Joint Session—Main Hall—Auditorium

Report of the Committee on Examination of Water and Sewage. JOHN F. NORTON, PH.D., The Upjohn Company, Kalamazoo, Mich.

Potability of Water from the Standpoint of Fluorine Content. H. V. SMITH, Assistant Agricultural Chemist, and DR. MARGARET C. SMITH, University of Arizona, Tucson, Ariz.

B. Coli vs. B. Aerogenes. Speaker to be selected.

Bacteriology and Shellfish. Speaker to be selected.

Dysentery-Like Outbreaks Attributed to Water Supplies. Speaker to be selected.

PUBLIC HEALTH EDUCATION AND CHILD HYGIENE SECTIONS

Joint Session—Exhibition Hall—Auditorium

Presiding: WILLIAM P. SHEPARD, M.D., *Chairman*, Public Health Education Section, Assistant Secretary, Welfare Division, Metropolitan Life Insurance Company, San Francisco, Calif.

The Scope of Health Education in Schools and in the Community at Large and the Activities Through Which It Functions. CLAIR E. TURNER, DR.P.H., Massachusetts Institute of Technology, Cambridge, Mass., MARY P. CONNOLLY, Director, Division of Health Education, Department of Health, Detroit, Mich., and ADELHEID ARSTEN. (Presented by WILLIAM P. SHEPARD, M.D.)

Tuesday, 9:30 A.M.

PUBLIC HEALTH EDUCATION AND CHILD HYGIENE SECTIONS (Cont.)

Joint Session—Exhibition Hall—Auditorium

Should School Medicine and School Nursing Be Chiefly Remedial Services to the Child or an Educational Experience?

For Education. DON W. GUDAKUNST, M.D., Director of School Health Service, Department of Health, Detroit, Mich.

Tuesday, 12:30 P.M.

DIPHTHERIA IMMUNIZATION

Special Luncheon Session—Ball Room—Huntington Hotel

Participants:

HUNTINGTON WILLIAMS, M.D., Commissioner of Health, Baltimore, Md.

J. N. BAKER, M.D., State Health Officer, Montgomery, Ala.

C. C. YOUNG, D.P.H., Director, Bureau of Laboratories, State Department of Health, Lansing, Mich.

W. T. HARRISON, National Institute of Health, Washington, D. C.

WILLIAM J. BELL, M.B., Deputy Minister of Health, Ottawa, Ont.

WILLIAM H. PARK, M.D., Director, Bureau of Laboratories, Department of Health, New York, N. Y.

Tuesday, 2:30 P.M.

PUBLIC HEALTH ENGINEERING

Third Session—Gold Room—Maryland Hotel

SYMPOSIUM ON MUNICIPAL PUBLIC HEALTH ENGINEERING

Report of the Committee on Municipal Public Health Engineering. *Chairman,* W. H. CARY, Department of Health, Detroit, Mich. (To be presented by title only.)

Amebic Dysentery in Chicago.

Engineering—JOEL I. CONNOLLY, Chief, Bureau of Sanitary Engineering, State Board of Health, Chicago, Ill.

Epidemiology—ARTHUR E. GORMAN, Engineer of Water Purification, Department of Public Works, Chicago, Ill.

Results of an Industrial Hygiene Survey in a Large Industrial City. J. J. BLOOMFIELD, Sanitary Engineer, U. S. Public Health Service, and W. SCOTT JOHNSON, Sanitary Engineer, Department of Health, St. Louis, Mo.

Use and Control of Hydro-Cyanic Acid Gas and Other Toxic Gases in Commercial Fumigation. AIME COUSINEAU, Chief Engineer, Department of Health, Montreal, Que., and F. G. LEE, Sanitary Engineer, Department of Health, Detroit, Mich.

Municipal Sanitary Conditions and Residual Typhoid. Speaker to be selected.

Tuesday, 2:30 P.M.

FOOD AND NUTRITION SECTION, CALIFORNIA ASSOCIATION
OF DAIRY AND MILK INSPECTORS, CALIFORNIA DAIRY
INDUSTRIES ASSOCIATION, AND THE
CALIFORNIA DAIRY COUNCIL

Joint Session—Main Hall—Auditorium

Presiding: WALTER H. EDDY, PH.D., *Chairman*, Food and Nutrition Section, Teachers College, Columbia University, New York, N. Y., and H. C. ERIKSEN, President, California Association of Dairy and Milk Inspectors, Health Department, Santa Barbara, Calif.

Address of Welcome to the Food and Nutrition Section. H. C. ERIKSEN.

Response. WALTER H. EDDY, PH.D.

Nutrition and Health and the Price of Milk. JAMES A. TOBEY, DR.P.H., Director, Health Service, The Borden Company, New York, N. Y.

Discussion. J. C. GEIGER, M.D., Health Officer, San Francisco, Calif.

The Rôle of Milk in Diets. W. W. BAUER, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago, Ill.

Report of the Committee on Milk and Dairy Products. *Chairman*, WILLIAM B. PALMER, Milk Inspection Association of the Oranges and Maplewood, Orange, N. J.

Public Health Regulations, Their Effect upon the Economics of Dairying. SAM H. GREENE, Secretary-Manager, California Dairy Council, San Francisco, Calif.

The Responsibility of the Inspector to the Consumer and the Dairy Industry. O. A. GHIGGOILE, Supervisor of Dairy Service, State Department of Agriculture, Sacramento, Calif.

Paper by California Dairy Industries Association. Title and speaker to be selected.

LABORATORY

Third Session—Lecture Room—Auditorium

SYMPOSIUM ON DIAGNOSTIC PROCEDURES AND REAGENTS

Presiding: W. D. STOVALL, M.D., *Chairman*, Committee on Diagnostic Procedures and Reagents, State Laboratory of Hygiene, Madison, Wis.

Significance of Bacteriological Methods in the Diagnosis and Control of Whooping Cough. PEARL KENDRICK, SC.D., Associate Director, and GRACE ELDERING, Bacteriologist, State Department of Health, Bureau of Laboratories, Western Michigan Division, Grand Rapids, Mich.

Biological Significance of Hemolytic Streptococci in Relation to the Etiology, Control and Treatment of Scarlet Fever and Other Hemolytic Streptococcus Infections. JULIA M. COFFEY, State Laboratory of Hygiene, Albany, N. Y.

The Application of the Neufeld Reaction to the Identification of Types of Pneumococci, with the Use of Antisera for Thirty-two Types. GEORGIA M. COOPER and ANNABEL W. WALTER, Bureau of Laboratories, Department of Health, New York, N. Y.

Laboratory Problems Associated with the Diagnosis and Epidemiological Investigations of Meningococcus Meningitis. SARA E. BRANHAM, M.D., PH.D., Senior Bacteriologist, National Institute of Health, Washington, D. C.

Tuesday, 2:30 P.M.

LABORATORY (Cont.)

Third Session—Lecture Room—Auditorium

Virulence Tests for Typhoid Bacilli and Antibody Relationships in Anti-typhoid Serums. JOHN F. NORTON, PH.D., and JOHN H. DINGLE, Sc.D., The Upjohn Company, Kalamazoo, Mich.

Studies on the Toxicity of Brilliant Green for Certain Bacteria. EDMUND K. KLINE, DR.P.H., Director of Laboratories, Cattaraugus County Department of Health, Olean, N. Y.

PUBLIC HEALTH EDUCATION

Second Session—Exhibition Hall—Auditorium

TECHNICS OF SPECIAL EXPERIENCES

Radio. J. L. POMEROY, M.D., Health Officer, and THEODORE SIERKS, Los Angeles County Health Department, Los Angeles, Calif.

Syndicated Material. NATHAN SENAL, DR.P.H., University of Michigan, Ann Arbor, Mich.

Health Bulletins. PAUL S. FOX, State Bureau of Public Health, Santa Fe, N. M.

Newspapers. WILLIAM F. HIGBY, Executive Secretary, California Tuberculosis Association, San Francisco, Calif.

Lectures and Demonstrations. HARRIET FITZGERALD, Berkeley Public Schools, Berkeley, Calif.

PUBLIC HEALTH ENGINEERING SECTION AND CALIFORNIA ASSOCIATION OF SANITARIANS

Joint Session—Main Dining Room—Maryland Hotel

The Value of Sanitary Inspection to Public Health. Speaker to be selected.

Formation of Sanitary Districts in Recreation Areas. Speaker to be selected.

Sterilization in Eating Houses. Speaker to be selected.

Bottled Beverage and Beer Parlors. Speaker to be selected.

Tuesday, 6:30 P.M.

PUBLIC HEALTH ENGINEERING

Dinner Session—Crystal Room—Huntington Hotel

Annual Engineers' Stag Dinner Party.

FOOD AND NUTRITION

Dinner Session—Gold Room—Maryland Hotel

Closed Session for Fellows and Members of the Section.

Section Business.

Tuesday, 6:30 P.M.

WESTERN BRANCH, A.P.H.A.

Dinner Session—Main Dining Room—Maryland Hotel

Address of the President of the Western Branch. J. L. POMEROY, M.D., Health Officer, Los Angeles County Health Department, Los Angeles, Calif.

Response. HAVEN EMERSON, M.D., President, American Public Health Association, Department of Public Health Administration, Columbia University, New York, N. Y.

Tuesday, 8:00 P.M.

WESTERN BRANCH, A.P.H.A.

General Session—Main Hall—Auditorium

International Relationships in Public Health. DR. RUFUS B. VON KLEINSMID, President, University of Southern California, Los Angeles, Calif.

Wednesday, 9:30 A.M.

VITAL STATISTICS

Second Session—Indiana Room—Auditorium

Section Business.

Postcensal Estimates of Population. C. E. BATSCHELET, Geographer, Bureau of the Census, Washington, D. C.

Current Mortality Releases. STEWART G. THOMPSON, D.P.H., Director, Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

The State Registrar and His Filing Problems. FRANCIS D. RHOADS, State Registrar of Vital Statistics, Seattle, Wash.

"Public Enemies" of Vital Statistics, in Consideration of the Provisions of the "Model Law." SHELDON L. HOWARD, Registrar of Vital Statistics, ELVA E. GORE, Assistant Registrar, and ROBERT H. WOODRUFF, M.D., Medical Assistant, State Department of Public Health, Springfield, Ill.

Accident Fatalities, 1933 (Report of the Committee on Accident Statistics). *Chairman*, W. THURBER FALES, Sc.D., Director, Bureau of Vital Statistics, State Department of Public Health, Montgomery, Ala.

INDUSTRIAL HYGIENE

Second Session—Lecture Room—Auditorium

Death Rates by Occupation. JESSAMINE S. WHITNEY, Statistician, National Tuberculosis Association, New York, N. Y.

SYMPOSIUM ON HEALTH HAZARDS IN THE SMELTING AND REFINING INDUSTRIES

Speakers and papers to be selected.

Wednesday, 9:30 A.M.

CHILD HYGIENE

Second Session—Crystal Room, Huntington Hotel

MATERNAL AND INFANT HYGIENE

What Can We Learn from Child Health Conditions in Europe? RICHARD A. BOLT, M.D., Director, Cleveland Child Health Association, Cleveland, O.

Discussion. WALTER H. BROWN, M.D., Professor of Hygiene, Stanford University, Palo Alto, and WILLIAM PALMER LUCAS, M.D., San Francisco, Calif.

The Maternal and Infant Problems of the Mexicans Residing in the Southwest. OLIVE B. CORDUA, M.D., Director, Division of Child Hygiene, City and County of San Diego, San Diego, Calif.

Discussion.

The Prenatal Clinic as a Routine Procedure of a County Health Department. N. C. KNIGHT, M.D., Sunflower County Health Department, Indianola, Miss.

Discussion. C. J. VAUGHN, M.D., Lexington, Miss.

Hawaiian Achievements in Child Health. PHILIP S. PLATT, PH.D., Director, Palama Settlement, Honolulu, T. H.

Discussion. GUY S. MILLBERRY, D.D.S., Dean, College of Dentistry, University of California, San Francisco, Calif.

Birth Control as a Public Health Problem. NADINA D. KAVINOKY, M.D., Director of Mothers' Clinics, Los Angeles County Health Department, Los Angeles, Calif.

Discussion. ANNA E. RUDE, M.D., Director, Bureau of Maternal and Child Hygiene, Los Angeles County Health Department, Los Angeles, Calif.

The Reduction of Maternal and Infant Mortality in Rural Areas. J. H. MASON KNOX, M.D., Chief, Bureau of Child Hygiene, State Department of Health, Baltimore, Md.

PUBLIC HEALTH NURSING

First Session—Assembly Room—Auditorium

Report of the Committee on Historical Review and Restatement of Objectives of the Public Health Nursing Section. *Chairman*, MARGUERITE WALES, R.N., General Director, Henry Street Visiting Nurse Service, New York, N. Y.

Report of the Committee on Membership and Stimulation of Fellowship in the Public Health Nursing Section. *Chairman*, ALMA HAUP, R.N., Associate Director, National Organization for Public Health Nursing, New York, N. Y.

Report of the Committee to Study Nursing Services in State Health Departments in Coöperation with the National Organization for Public Health Nursing. *Chairman*, MARION SNEELHAN, Director, Division of Public Health Nursing, State Department of Health, Albany, N. Y.

Section Business.

Medical Advisory Committees for Public Health Nursing Services. *Speaker to be selected.*

Discussion.

Wednesday, 9:30 A.M.

EPIDEMIOLOGY

Second Session—Gold Room—Maryland Hotel

Report on a Scarlet Fever Epidemic with Special Reference to Missed and Atypical Cases. GEORGE H. RAMSEY, M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y. (*Stereopticon Illustration.*)

The Reaction of Familial Contacts to Scarlet Fever Infection. J. E. GORDON, M.D., Medical Director, Division of Epidemiology, G. F. BADGER, Associate Epidemiologist, Department of Health, Detroit, and GEORGE B. DARLING, D.P.H., Associate Director, W. K. Kellogg Foundation, Battle Creek, Mich. (*Stereopticon Illustration.*)

Observations on Thirteen Years' Work of Diphtheria Immunization with Special Reference to Immunizing Children Under the Age of Six Months in Central New York and the Value of the Subsequent Schick Test. FREDERICK W. SEARS, M.D., District State Health Officer, Syracuse, N. Y. (*Stereopticon Illustration.*)

Diphtheria Morbidity and Mortality in Racial Groups in the United States. C. C. DAUER, M.D., Instructor of Preventive Medicine, Tulane University, New Orleans, La. (*Stereopticon Illustration.*)

An Outbreak of Milk Poisoning Due to a Toxin Producing Staphylococcus Which Was Found in the Udders of Two Cows. J. A. CRABTREE, M.D., Director, Division of Preventable Diseases, and WILLIAM LITTERER, M.D., Director of Laboratories, State Department of Health, Nashville, Tenn. (*Stereopticon Illustration.*)

HEALTH OFFICERS AND PUBLIC HEALTH EDUCATION

Joint Session—Main Hall—Auditorium

Presiding: WILLIAM P. SHEPARD, M.D., *Chairman*, Public Health Education Section, and Assistant Secretary, Welfare Division, Metropolitan Life Insurance Company, San Francisco, Calif.

Selling Health Department Members First on Health Education. HUNTINGTON WILLIAMS, M.D., Commissioner of Health, Baltimore, Md.

Discussion. JEAN V. LATIMER, Educational Secretary, Massachusetts Tuberculosis League, Boston, Mass.

The Technic of Selling the Health Department to the Public. K. W. GRIMLEY, Director of Health Education and Publicity, Jefferson County Board of Health, Birmingham, Ala.

Discussion. LEON BANOV, M.D., Health Officer, Charleston, S. C.

Wednesday, 12:30 P.M.

HEALTH OFFICERS

Luncheon Session—Main Dining Room—Maryland Hotel

COME AND FIND OUT!			

Wednesday, 12:30 P.M.

HEALTH OFFICERS (Cont.)

Luncheon Session—Main Dining Room—Maryland Hotel

Presiding: JOHN L. RICE, M.D., Commissioner of Health, New York, N. Y.

At the Answer Table will be found:

- J. N. BAKER, M.D., State Health Officer, Montgomery, Ala.
- HERMAN N. BUNDESEN, M.D., Commissioner of Health, Chicago, Ill.
- A. J. CHESLEY, M.D., State Health Officer, St. Paul, Minn.
- J. D. DUNSHEE, M.D., State Health Officer, Sacramento, Calif.
- J. C. GEIGER, M.D., Health Officer, San Francisco, Calif.
- JOHN P. KOEHLER, M.D., Health Commissioner, Milwaukee, Wis.
- THOMAS PARRAN, JR., M.D., State Health Commissioner, Albany, N. Y.
- JAMES ROBERTS, M.D., Medical Officer of Health, Hamilton, Ont.

Wednesday, 7:00 P.M.

SECOND GENERAL SESSION

Ball Room—Huntington Hotel

The Concern of the United States with Tropical Diseases. F. W. O'CONNOR, M.R.C.S., Associate Professor of Medicine, Columbia University, New York, N. Y.

Dancing.

Thursday, 9:30 A.M.

PUBLIC HEALTH NURSING

Second Session—Gold Room—Maryland Hotel

WHAT QUALITIES MAKE FOR SUCCESS IN A PUBLIC HEALTH NURSE

A Panel Session.

Foreman of the Jury: C.-E. A. WINSLOW, DR.P.H., Professor of Public Health, Yale University, New Haven, Conn.

Jurymen:

Director of a Public Health Nursing Service—Speaker to be selected.

A Course Director—MARY J. DUNN, R.N., Professor of Public Health Nursing, Vanderbilt University, School of Nursing, Nashville, Tenn.

A Superintendent of Schools—EDWIN LEE, Superintendent of Public Schools, San Francisco, Calif.

A Supervising Nurse—ANNA M. NEUKOM, R.N., Supervisor of School Nurses, State Education Department, Albany, N. Y.

A Layman—MARGARET B. HALE, President, Visiting Nurse Association of Pasadena, Ltd., Pasadena, Calif.

A Health Officer—WARREN F. DOWLER, M.D., State Health Commissioner, Richmond, Va.

Thursday, 9:30 A.M.

LABORATORY AND EPIDEMIOLOGY SECTIONS

Joint Session—Main Hall—Auditorium

SYMPOSIUM ON AMEBIC DYSENTERY

Clinical Amebiasis with Reference to Public Health. ALFRED C REED, M.D., Professor of Tropical Medicine, University of California, San Francisco, Calif.

The Epidemiology of Amebic Dysentery. J. C. GEIGER, M.D., Health Officer, San Francisco, Calif.

Laboratory Diagnosis of Amebic Dysentery. KARL F. MEYER, M.D., Professor of Bacteriology, The George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif. (*Stereopticon Illustration.*)

PUBLIC HEALTH ENGINEERING SECTION AND CALIFORNIA SEWAGE WORKS ASSOCIATION

Joint Session—Ball Room—Huntington Hotel

Influence of Public Works Administration on Sanitary Works Construction. Speaker to be selected.

Experiences with Sewage Farming in Southwest United States. V. M. EHLERS, Sanitary Engineer, State Board of Health, Austin, Tex., and F. C. ROBERTS, JR., State Sanitary Engineer, Phoenix, Ariz.

Reuse of Water for Industrial, Agricultural and Commercial Purposes. Speaker to be selected.

Present Status of Sea Outfalls and Ocean Disposal in the East and the West. Speaker to be selected.

Patents and Sewage Treatment Processes. Speaker to be selected.

Disposal of Wastes from:

Brewing—A. M. BUSWELL, Chief, State Water Survey Division, Urbana, Ill.

Wineries—F. E. DEMARTINI, JR., Sanitary Engineer, State Department of Public Health, Berkeley, Calif.

PUBLIC HEALTH EDUCATION

Third Session—Exhibition Hall—Auditorium

A Digest of Material Presented to Other Sections Which Is of Special Interest to Health Education Workers. IRA V. HISCOCK, Professor of Public Health, Yale University, New Haven, Conn.

Thursday, 12:30 P.M.

PUBLIC HEALTH EDUCATION

Luncheon Session—Main Dining Room—Maryland Hotel

A Discussion of Publicity Material Shown in the Health Education Exhibit. EVART G. ROUTZAHN, Russell Sage Foundation, New York, N. Y.

Thursday, 12:30 P.M.

CHILD HYGIENE

Luncheon Session—Crystal Room—Huntington Hotel

THE CHILDREN'S HOUR

Presiding: ELLEN STADTMULLER, M.D., Director, Bureau of Child Hygiene, State Department of Health, San Francisco, Calif.

Guests of Honor:

- THOMAS PARRAN, JR., M.D., State Health Commissioner, Albany, N. Y.
 KENDALL EMERSON, M.D., Managing Director, National Tuberculosis Association, and Executive Secretary, American Public Health Association, New York, N. Y.
 E. L. BISHOP, M.D., State Commissioner of Public Health, Nashville, Tenn.
 J. D. DUNSHEE, M.D., State Health Officer, Sacramento, Calif.
 JOHN L. RICE, M.D., Commissioner of Health, New York, N. Y.
 JOHN A. FERRELL, M.D., Associate Director, International Health Division, The Rockefeller Foundation, New York, N. Y.
 J. L. POMEROY, M.D., Health Officer, Los Angeles County Health Department, Los Angeles, Calif.
 DON W. GUDAKUNST, M.D., Director of School Health Service, Department of Health, Detroit, Mich.
 GUY S. MILLBERRY, D.D.S., Dean, College of Dentistry, University of California, San Francisco, Calif.
 A. J. CHESLEY, M.D., State Health Officer, St. Paul, Minn.
 WILLIAM PALMER LUCAS, M.D., San Francisco, Calif.
 GEORGE T. PALMER, D.P.H., Assistant to the Health Commissioner, Department of Health, New York, N. Y.
 HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Thursday, 2:30 P.M.

INDUSTRIAL HYGIENE

Third Session—Main Dining Room—Maryland Hotel

- Air Conditioning and Industrial Health. LEVERETT D. BRISTOL, M.D., DR.P.H., Health Director, American Telephone and Telegraph Company, New York, N. Y.
 Occupational Hazards in the Agricultural Industries. ROBERT T. LEGGE, M.D., Professor of Hygiene and University Physician, University of California, Berkeley, Calif.
 A Study of Silicosis in 106 Pottery Workers. PAUL A. QUAINANCE, M.D., Chief, Diagnostic Department, Golden State Hospital, Los Angeles, Calif.
 Tuberculosis Control in a Railway Health Insurance Program. PHILIP K. BROWN, M.D., Medical Director, Southern Pacific Hospital, San Francisco, Calif.

PUBLIC HEALTH ENGINEERING

Fourth Session—Exhibition Hall—Auditorium

Reports of Committees.

Thursday, 2:30 P.M.

LABORATORY

Fourth Session—Indiana Room—Auditorium

- A Study of Culture Media Used for Routine Diphtheria Cultures with a Suggested Modification of Loeffler's Blood Serum Medium.** ROSS L. LAYBOURN, Bacteriologist in Charge, Public Health Laboratory, State Board of Health, Topeka, Kans.
- Natural Immunity to Diphtheria in an Institution as Measured by the Schick Test and Blood Titration.** C. C. YOUNG, D.P.H., Director, and G. D. CUMMINGS, PH.D., Assistant Director, Bureau of Laboratories, State Department of Health, Lansing, Mich.
- Diphtheria Studies II. The Use of Intradermal Injections of Toxin-Toxoid Mixtures in Diphtheria Immunization.** W. E. BUNNEY, PH.D., State Department of Health, Lansing, Mich.
- An Acute Epizootic of Septicemic and Pneumonic Plague in Ground Squirrels.** W. H. KELLOGG, M.D., Chief, and JOHN F. KESSELL, PH.D., Bureau of Laboratories, Department of Public Health, Berkeley, Calif.
- Dysenteriae and Diarrheas of Childhood in the Near East.** E. W. DENNIS, M.D., Associate Professor of Bacteriology and Parasitology, American University of Beirut, School of Medicine, Beirut, Syria.
- The Epidemiological Value of Isolating Bacteriophage in Outbreaks of Intestinal Infection.** ROY F. FLEEMSTER, M.D., DR.P.H., Assistant Director, Antitoxin and Vaccine Laboratory, State Department of Health, Boston, Mass.

HEALTH OFFICERS

Third Session—Gold Room—Maryland Hotel

TUBERCULOSIS AS THE HEALTH OFFICER'S OPPORTUNITY

- Epidemiology of Tuberculosis.** Speaker to be selected.
- A Modern Set-Up of the Tuberculosis Program in a Health Department.** REGINALD H. SMART, M.D., Tuberculosis Division, Los Angeles County Health Department, Los Angeles, Calif.
- Childhood Tuberculosis and What It Means.** MARGARET W. BARNARD, M.D., Director, District Health Administration, Department of Health, New York, N. Y.
- The Future Program of the National Tuberculosis Association.** KENDALL EMERSON, M.D., Managing Director, National Tuberculosis Association, and Executive Secretary, American Public Health Association, New York, N. Y.
- Discussion.** WILLIAM F. HIGBY, Executive Secretary, California Tuberculosis Association, San Francisco, Calif., and JAMES A. CRABTREE, M.D., Director, Division of Preventable Diseases, State Department of Health, Nashville, Tenn.

FOOD AND NUTRITION

Second Session—Assembly Room—Auditorium

- The Evolution of Meat Inspection.** GEORGE GORDON, D.V.S., Meat Inspection Bureau, State Department of Health, Sacramento, Calif.

Thursday, 2:30 P.M.

FOOD AND NUTRITION (Cont.)

Second Session—Assembly Room—Auditorium

Public Health Aspects of Dried Foods. PAUL F. NICHOLS, University of California, Berkeley, Calif.

Fluorine Toxicosis, A Public Health Problem. DR. MARGARET CAMMACK SMITH, University of Arizona, Tucson, Ariz.

Health Problems Connected with the Ethylene Treatment of Fruits. E. M. CHACE, Laboratory of Fruit and Vegetable Chemistry, U. S. Department of Agriculture, Los Angeles, Calif.

Salmon Inspection. E. D. CLARK, PH.D., Director, and RAY W. CLOUGH, PH.D., Northwestern Laboratory, National Cannery Association, Seattle, Wash.

Report of Committee on Foods. *Chairman*, CARL R. FELLERS, PH.D., Massachusetts State College, Amherst, Mass.

LABORATORY

Fifth Session—Lecture Room—Auditorium

Further Studies on the Colon Group. EDMUND K. KLINE, DR.P.H., Director of Laboratories, Cattaraugus County Department of Health, Olean, N. Y.

A Study of the Value of Laboratory Examination of Milk Handlers. EARLE K. BORMAN, Assistant Director, FRIEND LEE MICKLE, Director, and D. EVELYN WEST, Chief Microbiologist, Bureau of Laboratories, State Department of Health, Hartford, Conn.

A Solution of the Streptococcus Carrier Problem. C. W. BONYNGE, M.D., Director, Milk Commission of the Los Angeles County Medical Association, Pasadena, Calif.

Statistical and Serological Studies of Correlated Human and Bovine Brucellosis. R. V. STONE, D.V.M., Director, Bureau of Laboratories, Los Angeles County Health Department, Los Angeles, Calif.

The Relation of the Action of Chlorine to Bacterial Death. C. S. MUDGE, Associate Professor of Dairy Industry, University of California, College of Agriculture, Davis, Calif.

THE THIRD INSTITUTE ON HEALTH EDUCATION

August 31, September 1, 2 and 3

Director: IAGO GALDSTON, M.D.

Instructors: IAGO GALDSTON, M.D., CHARLES E. SHEPARD, M.D.,
HERBERT R. STOLTZ, M.D.

HEALTH EDUCATION IN SCHOOLS

In the four didactic sessions, the Round Table and the Summary sessions, students will help formulate:

THE THIRD INSTITUTE ON HEALTH EDUCATION (Cont.)

- A clear definition of the problem of school health education
- A definition of the curricula of the lower, middle and high school grades, as well as the psychologic character and the educational implication of each of the three groups of grades
- An effective technic in school health education
- The proper relationship of the home, the public and the private health organizations to health education in the school
- The relation of commercial organizations to the school health program
- A plan for dealing with the uninvited guest, the sound and unworthy commercial propaganda that worms its way into the school.

Registration fee \$5.00

MEETINGS OF OTHER ORGANIZATIONS

CONFERENCE OF STATE LABORATORY DIRECTORS

Sunday, September 2, 12:30 P.M. Luncheon. University Club.

WESTERN BRANCH, AMERICAN PUBLIC HEALTH ASSOCIATION

Sunday, September 2, 8:30 A.M. Business Meeting. Lecture Hall, Auditorium.

Sunday, September 2, 12:30 P.M. Luncheon. Main Dining Room, Maryland Hotel.

Sunday, September 2, 2:30 P.M. Business Meeting. Lecture Hall, Auditorium.

Tuesday, September 4, 6:30 P.M. Dinner. Main Dining Room, Hotel Maryland. (See page 789.)

Tuesday, September 4, 8:00 P.M. General Session, Main Hall, Auditorium. (See page 789.)

CALIFORNIA ASSOCIATION OF DAIRY AND MILK INSPECTORS

Monday, 2:30 P.M. Hotel Green

Call to Order. H. C. ERIKSEN, President, California Association of Dairy and Milk Inspectors, Department of Health, Santa Barbara, Calif.

Announcements. ERNEST TEW, Chief Inspector, and *Chairman*, Committee on Arrangements and Entertainment, Department of Health, Pasadena, Calif.

Address of Welcome. Speaker to be selected.

Response. H. C. ERIKSEN, President, California Association of Dairy and Milk Inspectors.

Reports of Standing Committees—Legislation, Milk Plant Practice, Dairy Farm Methods, Dairy and Milk Plant Equipment, Laboratory Methods, Publicity, Resolutions and Public Relations, Membership Committee.

Adjournment to attend the Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association, Main Hall, Auditorium.

CALIFORNIA ASSOCIATION OF DAIRY AND MILK INSPECTORS (Cont.)

Tuesday, 9:30 A.M. Hotel Green

Business

President's Announcements

Report of the Secretary-Treasurer

Report of the Association's Magazine "The Milk Inspector"

Election of Officers

Discussion of Future Policy of "The Milk Inspector"

Round Table Discussion

Tuesday, 11:45 A.M.-1:30 P.M.

Barbecue at the Supreme Dairy Farm. Members of the Food and Nutrition Section of the American Public Health Association are invited.

Tuesday, 2:30 P.M.

Joint session with the Food and Nutrition Section, the California Association of Dairy Industries and the California Dairy Council. (See page 787.)

Wednesday, 9:30 A.M. Hotel Green

Standard Milk Ordinances of the United States Public Health Service and Its Operation. **LESLIE C. FRANK**, Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

No Title. **DR. J. J. FREY**, Golden State Company, San Francisco, Calif.

No Title. **DR. C. L. ROADHOUSE**, State College of Agriculture, Davis, Calif.

AMERICAN SOCIAL HYGIENE ASSOCIATION

Monday, 9:30 A.M. Ball Room, Huntington Hotel. Joint Session with the Public Health Nursing Section. (See page 780.)

MUNICIPAL SANITATION, EDITORIAL COMMITTEE

Monday, 12:30 P.M. Luncheon.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

All persons interested in school health work invited to participate.

Tuesday, 2:00 P.M., Assembly Room, Auditorium.

Greetings from the President. **A. O. DEWEESE, M.D.**, Director, Health and Physical Education, Kent State Normal College, Kent, O.

Aspects of Heart Diseases in School Children. **HENRY H. LISSNER, M.D.**, President, Los Angeles School Heart Board, Los Angeles, Calif.

Discussion. **MAURICE H. ROSENFELD, M.D.**, Cardiologist.

Health Supervision of College Students. **A. O. DEWEESE, M.D.**, Director, Health and Physical Education, Kent State Normal College, Kent, O.

Review of Recent Studies on Poliomyelitis. **BEATRICE HOWITT**, Associate in Research Medicine, The George Williams Hooper Foundation for Medical Research, San Francisco, Calif.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS (Cont.)

Exercises for School Children with Heart Disease. SVEN LOKRANTZ, M.D.,
Director of Health, Los Angeles City Schools, Board of Education, Los Angeles,
Calif.

General Discussion on School Health Problems.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Monday, 6:30 P.M. Main Dining Room, Maryland Hotel. Dinner.

CALIFORNIA ASSOCIATION OF DAIRY INDUSTRIES

Tuesday, 2:30 P.M. Main Hall, Auditorium. Joint Session with the Food and Nutrition Section, the California Association of Dairy and Milk Inspectors, and the California Dairy Council. (See page 787.)

CALIFORNIA DAIRY COUNCIL

Tuesday, 2:30 P.M. Main Hall, Auditorium. Joint Session with the Food and Nutrition Section, the California Association of Dairy and Milk Inspectors, and the California Association of Dairy Industries. (See page 787.)

CALIFORNIA ASSOCIATION OF SANITARIANS

Tuesday, 2:30 P.M. Main Dining Room, Maryland Hotel. Joint Session with the Public Health Engineering Section. (See page 788.)

JOHNS HOPKINS ALUMNI

Wednesday, 8:00 A.M. Grill Room, Maryland Hotel. Breakfast.

HARVARD UNIVERSITY ALUMNI

Wednesday, 8:00 A.M. Main Dining Room, Maryland Hotel. Breakfast.

DELTA OMEGA

Wednesday, 12:30 P.M. Grill Room, Maryland Hotel. Luncheon.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY ALUMNI

Thursday, 8:00 A.M. Grill Room. Maryland Hotel. Breakfast.

CALIFORNIA SEWAGE WORKS ASSOCIATION

Thursday, 9:30 A.M. Ball Room, Huntington Hotel. Joint session with Public Health Engineering Section. (See page 793.)

ASSOCIATION NEWS

PASADENA AND ALL CALIFORNIA AWAITS YOU

IT has been said that people who have never been to California desire to go there and those who have been to California desire to return. There is a distinct charm in the natural resources of the state and many members of the American Public Health Association are looking forward not only to the Sixty-third Annual Meeting to be held in Pasadena September 3-6, but they are also anticipating visits to world famous outing places and recreational areas in California.

If there be artists among such members, they can find deep inspiration at the Huntington Library in Pasadena, where Gainsboroughs, Romneys, and Turners, as well as other old masters, are represented in one of the most notable collections in the United States. The Palace of the Legion of Honor in San Francisco, located on an eminence overlooking the Pacific Ocean and the Golden Gate, also contains most interesting displays of both ancient and modern art.

Members of the Association who are sportsmen will find excellent golf courses in the vicinity of Pasadena and Los Angeles, as well as all of the other larger cities of the state. Deep sea fishing can be had off the southern California coast and many varieties of game trout are found in the mountain lakes and streams of the state. Those who enjoy swimming and water sports will find all facilities for ocean bathing at the beaches, coast resorts, and at Catalina Island.

Visitors who are interested in the early history of California will want to see Sutter's Fort at Sacramento, which was established by Captain John A.

Sutter in 1839, as the first outpost of white civilization in the great interior of California. It was to one of the rooms at this fort that James W. Marshall in January, 1848, brought the first flakes of pure gold which he showed to Sutter. Since that eventful moment, the history of California and the West has proceeded at a furious speed. The fort, now restored to its original state, is maintained as a museum to house a number of priceless relics of pioneer and gold rush days.

Capitol Park, in which is located the State Capitol erected in the 60's, is still one of the most attractive parks in California. It is famed for its remarkable collection of trees, plants, and flowering shrubs.

Students of history may want to visit the old missions, of which there are many in excellent state of preservation. At San Juan Capistrano, effective restorations have been made, making that mission one of the most attractive of all. Others are located in San Gabriel, Santa Barbara, San Luis Obispo, San Miguel, Santa Clara, Monterey, Carmel, San Juan Bautista, and many other localities. In some of these old missions, vestments worn by Father Junipera Serra, who founded the missions, are to be seen. Silken altar cloths, embroidered by nuns in Spanish cloisters, censers of hand-beaten silver wrought by early day Spanish artisans are to be found in some of these old places of worship.

Astronomers, if there be such among the membership, will enjoy a trip to Mount Wilson, where a new largest telescope is in course of construction. At Lick Observatory on

Mount Hamilton, near San Jose, excellent facilities are also provided for star-gazers.

Those who are in a hurry will find fast airplanes that will take them from city to city almost anywhere along the Pacific Coast.

The National parks maintained by the U. S. Forest Service will attract many to California. The Yosemite, General Grant, Sequoia, and Lassen Volcanic national parks are outstanding places of interest. The beauties of the Yosemite Valley have been described and pictured until they have become well known to almost everyone who reads. Nevertheless, a visit to this valley provides a most pleasurable realization. John Muir has made this valley famous in his books and those who anticipate going to Yosemite should read his description.

Persons interested in nature study should read, particularly, Muir's' chapter on the water ouzel, one of the most interesting of all birds. It builds its nest at the water's edge under the spray of a waterfall. Although its feet are not webbed, it dives into the clear cold fast-running streams for part of its food supplies. In flying it always follows the water course, never cutting across a bend in the stream but following the water always. The water ouzel is continually in motion, always singing, and is unquestionably one of the most interesting of all birds. Nature lovers should plan to visit Yosemite, to see the water ouzel in its natural habitat.

The Sequoia National Park has thousands of the Sequoia gigantea, the oldest and largest living things on earth. The size of these trees is unbelievable. No imaginative process can conceive of their gigantic proportions. Their bark is of the radiant cinnamon red color and they tower into the sky to amazing heights. From both Yosemite, Sequoia, and General Grant

national parks pack trips can be made into the high Sierras. These can be 1 day, 3 day, or 7 day trips, and they cover some of the most interesting mountain scenery in the world—snow-capped peaks, glaciers, mountain lakes, and roaring streams. The Mount Lassen National Park is famous for its volcanic peak, the only active volcano in continental United States. Trips can be made to the very summit and in this volcanic region, with its cinder cones, boiling lakes and devils' kitchen of vari-colored boiling mud pots, there is great fascination.

A colorful place is Agua Caliente, across the Mexican border from San Diego. Here there is a huge casino and modern hotel. It is a little Monte Carlo where good food can be obtained in attractive surroundings. Close by is Tia Juana, sordid but interesting because of its real Mexican atmosphere. San Diego itself is a most charming city. Its public parks are magnificent and its climate is delightful. Here Ramona's home, made famous by Helen Hunt Jackson, can be visited. Extending all over California are magnificent highways, most of which belong to the state highway system. They are kept in excellent repair and provide easy access to all places of interest. Members of the Association who drive their own cars to California can anticipate a great treat in driving over these smooth concrete ribbons.

Los Angeles and San Francisco provide every attribute for metropolitan entertainment, good food, and luxurious hotels. Rates are low now, and there are ample opportunities for keen enjoyment of the cosmopolitan life that is found in both of these large cities.

In San Francisco, engineers will marvel at the two enormous bridges now under construction. One will span the Golden Gate and the other will cross the San Francisco Bay from Oakland to San Francisco. Millions are

being spent in their construction, and novel engineering methods employed.

Within walking distance of the hotels in San Francisco is that cluster of steep-pitched streets where the largest colony of Chinese, outside of China, lives its own life. Here the shops, the smells, the sounds, even the architecture, suddenly become truly Oriental; strange music issues from theatres where stars from Canton and Shanghai appear. Wise globe-trotters save their money for San Francisco's Chinatown. In its many gay bazaars are bargains not to be matched in the treaty ports of China itself, and you will like the Chinese flappers, dainty, chic, strange blend of exotic East and Western smartness. Of particular interest to visitors are the

joss houses; the telephone exchange, where calls are made by name, necessitating the memorizing by Chinese girl operators of more than 2,000 subscribers' names; the jewelers at work on the side streets; and the newspapers which are composed by hand from thousands of pieces of type, each representing a sign word.

Californians await opportunities to play hosts to Association members from other states. Full facilities for recreation and entertainment are available, and health officers in all parts of the state are ready to assist all visitors to the September meeting in finding the type of recreation indicated by their individual taste. We invite you to partake of our western hospitality.

OF SCIENTIFIC INTEREST IN PASADENA

THE Pasadena Local Committee is offering to the members of the American Public Health Association an opportunity in September to visit many places of outstanding importance in scientific endeavor. Following are only some of the many places public health workers will find of special interest.

LOS ANGELES COUNTY HOSPITAL

On April 15, 1934, the New Acute Unit Building of the Los Angeles County Hospital was dedicated. This building was erected at a cost of approximately \$13,000,000 and is devoted to the care of acutely ill indigent residents of Los Angeles County. Communicable diseases and psychopathic cases are not treated in this building.

The building contains no ward having more than 8 beds. The typical visiting unit contains 28 beds, divided into four 6-bed wards, one 2-bed ward, and two 1-bed wards. Twelve hundred beds from these wards can be wheeled on to roof areas without elevator transporta-

tion. The building has a normal working capacity of 2,444 and an ultimate capacity of 3,600 beds. The two top-most floors are reserved for emergency epidemics or disasters.

The building has two independent water supplies from different reservoirs and four independent electrical services from widely separated plants. It is connected into two separate sewer lines.

The unit is of steel frame with floors and walls of reinforced concrete. It contains 20 stories, the largest of which is the main floor containing 186,200 square feet. There are 16,500,000 cubic feet in the building and it is earthquake proof. It contains more than 5,000 hollow metal doors, more than 2,700 hollow metal cabinets and 5,400 lockers. It has more than 35 miles of travertite base. A total of more than 600,000 sacks of cement was used in the 90,000 cubic yards of concrete which the building contains. Electric, plumbing, and heating contracts called for 108 miles of electric

conduits, 720 miles of wire and cables, and 250 miles of pipe lines. More than 38,000 keys are ticketed and filed in the key filing cases. There were 620,000 square yards of plastering used, of which 85,000 square yards is acoustical plaster. Sixty per cent of the wall and ceiling surfaces in the wards were plastered with this plaster. This compares with 15 per cent sound-proofed surfaces in other hospitals.

More than 16,000 meals a day can be served in the building from a central kitchen. Every patient is served at his bed from food carts which are set up in the central kitchen and returned with trays to a central dish-washing plant. One hundred food carts, each capable of carrying 36 trays, are garaged and serviced in the central kitchen.

HEALTH CENTERS

The new Alhambra Health Center, one of the most recently constructed of the Los Angeles County Health Centers, is regarded as a remarkable example of a modern solution to the health and welfare problems of an area. The Health Center Plan, originated by the Los Angeles County Health Department in 1924, aims to provide a number of completely equipped and staffed institutions located at strategic points in the county to obviate long distance transportation to a main health office for clinical, medical, health educational, or emergency service.

The Alhambra Health Center, located approximately 4 miles south of Pasadena and 8 miles northeast of the Hall of Justice, Los Angeles, is constructed along the California-Spanish lines of architecture—white stucco walls, 2-story, tile roof—a cheery departure from conventional style in public medical buildings. Its equipment comprises X-ray for tuberculosis diagnosis, special dental apparatus for preventive dentistry among school children, eye-ear-nose-throat instruments for physical

examination, orthopedic apparatus including large tile pool for poliomyelitis cases, emergency operating rooms and equipment with adjoining wards and kitchen, metabolism and cardiology instruments used in prenatal work, laboratory, fluoroscope, venereal disease equipment, and many other types of apparatus specially designed and arranged from a public health standpoint rather than that of a medical institution. Maternal and child hygiene conferences meet regularly at the Health Center. Headquarters for the local district staff of health officers, sanitary inspectors, public health nurses, and social service workers are maintained in the building.

The East Side Health and Welfare Center, located 7 miles east of Los Angeles, is mother of the chain of health centers extending throughout Los Angeles County. Its equipment and staff are organized in the same way as those of the Alhambra institution. The East Side building is unique in the fact that it serves what is believed to be the largest unincorporated area in the United States—a population of approximately 100,000 in an area of 40 square miles. Central administrative offices of the County Health Department's bureaus of nursing, child hygiene, and sanitation are housed in this building, due to lack of space at central headquarters in Los Angeles.

PSITTACOSIS LABORATORY

The U. S. Public Health Service, in the late fall of 1932, established in Pasadena a Psittacosis Laboratory under the direction of Senior Surgeon H. E. Hasseltine. The purpose of this laboratory is for the study and control of the disease, psittacosis. The laboratory also coöperates with physicians and health officers throughout the country in establishing the diagnosis of this disease in birds and in human cases. The building which the laboratory occupies

was formerly the Isolation Hospital, and was kindly loaned to the Public Health Service by the City of Pasadena.

SEWAGE DISPOSAL PLANT OF PASADENA

The continued and increasing interest, not only on the part of sanitary engineers but also by the general public, in the question of complete and sanitary disposal of municipal sewage, warrants a visit to the Tri-City sewage treatment plant serving the cities of Pasadena, Alhambra, South Pasadena, and San Marino, a combined population of about 124,000. This plant has been in continuous operation since 1924 and at the present time is treating an average annual flow of approximately 3 billion gallons and producing organic fertilizer as a by-product. The activated sludge process is conceded to be the most efficient method, from the results obtained, for the disposal of sewage.

The effluent or water from the sedimentation tanks is very clear, and the reduction in bacteria is 99 per cent plus. Raw sewage contains approximately 5 million bacteria per c.c. The effluent from the sedimentation tanks contains approximately 200,000 bacteria per c.c. The reduction of solids is 90 to 95 per cent. In order that the effluent may be still further purified bacterially, so as to render it harmless before it leaves the plant, it is chlorinated, thereby reducing the bacteria to not more than 300 per c.c. The requirements of the California State Board of Health permit 10,000 colonies per c.c.

Disposition of the excess sludge has been the principal problem connected with all sewage disposal. Pasadena has solved the problem by converting a nuisance into a valuable and increasingly popular fertilizer known as "Nitroganic." The annual production is approximately 3,000 tons, or about 1 ton of dried commercial fertilizer per million gallons of sewage, or about 50

pounds of dried fertilizer per annum per unit of population served. The material is sterile and does not and cannot transmit disease. This is evidenced by the fact that while the process has been going on for more than 7 years, no case of infection or vocational illness has been experienced by the plant operatives. This, however, is not surprising, since the fertilizer consists of totally new chemical compounds, formed by the treatment to which it has been exposed.

BEVERLY HILLS WATER TREATMENT PLANT

This modern water treatment plant is housed in a beautiful building befitting the surroundings. The primary object of the plant is to rid well water supply of sulphur and iron and their microorganisms; beggiatoa and crenothrix, the sulphur and iron algae or bacteria and also manganese bacteria which imparted bad taste and odor to water.

W. K. KELLOGG RADIATION LABORATORY

During the past few years, high voltage roentgen-ray equipment has been made available, for clinical purposes, which operates satisfactorily at potentials of 600 kv. or higher. Apparatus of this type was first constructed 3 years ago by Lauritsen and his co-workers at the California Institute of Technology. The physical, biological, and clinical factors pertaining to such apparatus seem to be of increasing interest to the roentgen therapist. Up to September 25, 1933, clinical experience at the California Institute had been limited to 285 patients. Only inoperable cases are accepted.

The equipment used was designed and constructed by Lauritsen and his associates at the W. K. Kellogg Laboratory. The high potential source consists of 2 transformers, each rated at 750 kv. root-mean-square at 30 ma., and therefore each is able to operate at a peak voltage of 1,000,000. One trans-

former is on the bridge and the other is in the pit of the laboratory. The middle portion of the tube is grounded and one of the transformers is connected to each end of the tube. The tube itself is 30 feet long and protrudes through the treatment room. It is constructed of glass cylinders protected internally with steel shields. A gold target is situated at the lower end of the upper electrode.

MT. WILSON OBSERVATORY

Located on the summit of mile-high Mt. Wilson, the Mt. Wilson Observatory of the Carnegie Institution of Washington, D. C., is regarded as the world's foremost center of astronomical research. The world's largest telescope is in-

cluded in its equipment. Aside from the observatory, the summit affords an inspiring view of the San Gabriel Valley and the Coast line beyond.

DAIRIES

For those interested, visits are also being arranged to prominent dairies and dairy plants in southern California, showing modern methods of milk control, production, etc.

GENERAL INTERESTS

In addition to the foregoing, plans are being made for registrants to avail themselves of the opportunity of visiting many other places of general interest.

MAKE YOUR RESERVATION EARLY

.....(*Cut off on this line and mail to the hotel of your choice—See p. 806*).....

HOTEL RESERVATION BLANK FOR PASADENA MEETING AMERICAN PUBLIC HEALTH ASSOCIATION

50 WEST 50TH STREET, NEW YORK, N. Y.

Hotel Constance

(Capacity, 164 Rooms)

Single room, with bath, \$2.00
 Double room, with bath, \$3.00

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, pro-

viding such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Pasadena will be elected for the three-year term, 1934-1937.

Felix J. Underwood, M.D., Jackson, Miss.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

- Lloyd F. Allen, M.D., 44 S. Main St., Pittsford, N. Y., Health Officer
 Carlos Diez del Ciervo, M.D., Avenida Sur 153, Caracas, Venezuela, Public Health Director (Assoc.)
 Thomas J. Danaher, M.D., 55 Main St., Torrington, Conn., Health Officer of Harwinton
 Robert L. Hunter, M.D., Boone County Health Dept., Madison, W. Va., Health Officer
 George E. Johnson, M.D., 5341 Chester Ave., Philadelphia, Pa., Chief, Division of Communicable Diseases, Dept. of Health
 Kenneth B. Moore, M.D., Dept. of Health, Flint, Mich., Assistant Health Officer
 Joseph H. Page, M.D., 1016 Medical Arts Bldg., Houston, Tex., County Health Officer
 Reece M. Pedicord, M.D., City-County Health Dept., Wheeling, W. Va., Health Commissioner
 T. C. Rice, M.D., Franklin, Tenn., Associate Director, Unison County Health Dept.
 Leopold M. Rohr, M.D., 106-25 New York Ave., Jamaica, L. I., N. Y., District Health Officer
 W. Carey Sanford, M.D., Cleveland, Tenn., Director, Bradley County Health Unit
 Madison U. Stoneman, M.D., 280 W. Fifth St., Pomona, Calif., District Health Officer

Laboratory Section

- Sara E. Branham, M.D., Ph.D., National Institute of Health, Washington, D. C., Senior Bacteriologist, U. S. Public Health Service
 Floyd H. Eggert, M.S., Woodworth, Wis., Director, Biological Labs., U. S. Standard Products Co.
 Herbert G. Johnstone, Ph.D., Pacific Institute of Tropical Medicine, Hooper Foundation, San Francisco, Calif., Research Associate in Tropical Medicine
 Louis L. Høstemyer, M.D., Community Hospital, Newark, N. Y., Bacteriologist in charge, Wyoming County Laboratory
 Jennie Riggs, 701 Cedar St., Nashville, Tenn., Laboratory Technician, State Dept. of Public Health

Vital Statistics Section

- Delmer E. Batcheller, M.A., 613 City Hall, Buffalo, N. Y., Registrar of Vital Statistics

Robert H. Woodruff, M.D., State Dept. of Public Health, Springfield, Ill., Medical Assistant, Division of Vital Statistics

Public Health Engineering Section

- Mario L. Ferreira, 110 Ferreira Nobre, Rio de Janeiro, Brazil, S. A., Chief Engineer, Federal Laboratory (Assoc.)
 William H. Henning, 1382-20 Ave., San Francisco, Calif., Chief, Division of Plumbing, etc., Dept. of Public Health
 Howard D. Schmidt, B.E., State Dept. of Public Health, Nashville, Tenn., Associate Sanitary Engineer

Industrial Hygiene Section

- Alfred H. Whittaker, M.D., 1394 E. Jefferson, Detroit, Mich., Chairman, Sub-Committee on Public Health, Detroit Board of Commerce

Food and Nutrition Section

- Harry C. Moore, 3716 W. First St., Los Angeles, Calif., Chief, Los Angeles Station, U. S. Food and Drug Administration

Child Hygiene Section

- Wilbur S. Stakes, M.D., 35 Railroad Ave., Patchogue, L. I., N. Y., School Physician

Public Health Education Section

- Paul W. Allen, Ph.D., 344 Forest Hills Blvd., Knoxville, Tenn., Head, Dept. of Bacteriology, University of Tennessee
 Helen E. Charles, 340 N. Oxford, Los Angeles, Calif., School Nurse
 May S. McCormick, P. O. Box 119, Jacksonville, Fla., Executive Secretary, Florida Tuberculosis and Health Assn.
 Grace V. Plum, R.N., P.H.N., San Jose State Teachers College, San Jose, Calif., Instructor and College Nurse
 Leigh E. Sloan, M.D., 317 E. Manchester Ave., Inglewood, Calif., on staff, Dept. of Communicable Diseases, Los Angeles General Hospital

Public Health Nursing Section

- Henrietta M. Adams, R.N., Harborview Hall, Seattle, Wash., Educational Director, Harborview Division, University of Washington School of Nursing
 Mary L. Allen, R.N., State Dept. of Health, Seattle, Wash., Chief, Division of Public Health Nursing and Child Hygiene

Laurene C. Fisher, R.N., P.H.N., Kanawha County Health Office, Charleston, W. Va., Public Health Nurse
 Helen S. Hartley, R.N., P.H.N., 130 S. American St., Stockton, Calif., Supt. of Nurses, San Joaquin Local Health District
 Mrs. Millard Given, Ripley, Tenn., Public Health Nurse
 Carol H. Kidder, A.B., P.H.N., Y.W.C.A., Sacramento, Calif., Public Health Nurse, City Health Dept.
 Rose C. Laning, P.H.N., 6 Bungalow Park, S. Charleston, W. Va., Public Health Nurse
 Mary D. Osborne, R.N., Old Capitol, Jackson, Miss., Associate Director, Public Health Nursing and Child Hygiene
 Katherine Vivian, R.N., 3323 N. Central Ave., Phoenix, Ariz., Maricopa County Health Nurse
 Dorris Weber, R.N., 5475 Cobanne Ave., St. Louis, Mo., Educational Director, Visiting Nurse Assn.

Epidemiology Section

Elliott F. Harrison, M.D., Craig Court, Frank-

lin, Tenn., Chest Clinician, Tuberculosis Division, State Dept. of Health
 Romero Hernan, M.D., M.Sc., Chilean Consulate, 21 West St., New York, N. Y., Student (Assoc.)
 Harold G. Trimble, M.D., 508-16 St., Oakland, Calif., Chief, Tuberculosis Clinics, Oakland Health Center
 Samuel L. Wadley, M.D., C.P.H., 883 N. Barksdale St., Memphis, Tenn., Director, Division of Communicable Diseases, Dept. of Health

Unaffiliated

Franklin Farman, M.D., 727 W. Seventh St., Los Angeles, Calif., Consulting Physician (Assoc.)
 Hugo A. Freund, M.D., 62 Kirby Ave. W., Detroit, Mich., President, Board of Trustees, Children's Fund of Michigan (Assoc.)
 Emmett R. Gahn, 435 E. Henrietta Rd., Rochester, N. Y., Chief, Monroe County Dept. of Sanitation
 Lyell C. Kinney, M.D., 1831-4th Ave., San Diego, Calif. (Assoc.)

DECEASED MEMBERS

George L. Pearson, M.D., Youngstown, O., Elected Member 1920
 D. M. Adams, M.D., Panama City, Fla., Elected Member 1927
 Albert B. Tonkin, M.D., Riverton, Wyo., Elected Member 1932
 William H. Welch, M.D., Baltimore, Md., Elected Member 1917, Fellow 1923
 Florin J. Amrhein, Ph.D., Boston, Mass., Elected Member 1924
 E. W. Kelly, C.E., Duluth, Minn., Elected Member 1930
 Floyd P. Smith, M.D., Trenton, Tenn., Elected Member 1932

What Others Say About Us

(Taken from the Medical Officer—March 31, 1934)

The Year Book of the American Public Health Association (1933-34) was published as a supplement to the AMERICAN JOURNAL OF PUBLIC HEALTH of February, 1934. The association has no exact counterpart in this country, because in Britain the Ministry of Health (or the Department of Health for Scotland) has powers to co-ordinate the health functions of local units, and to fix standards of minimum requirements which are much more extensive than exist in most countries, or than could possibly exist in such countries as France with its "Departments," or the United States with its semi-independent States. We have numberless health associations and societies work-

ing with the object of educating the populace to look after its own health and to demand the State to protect it, and also to advise and influence the State itself, but they are none of them absolutely necessary because the service itself is cohesive and develops from its own experiences. In America this cohesion and interdependence of all local units hardly exists. The Federal Government has certain powers over all the States, the States over the counties, and the counties over the smaller communes, but all these units are in the main independent. The American Public Health Association is the chief body in promoting unity of design and action. It has no power save that of persuasion, but

this in a body so comprehensive and united and so efficiently organized is powerful, if not compelling. In the year book for 1933-34 the association publishes an official declaration of its attitude on the "Standard Minimum Functions and Suitable Organisation of Health Activities" which is worthy of our close study, for it reveals the goal towards which the association is driving, to establish throughout the Republic a uniform system of health activities which in most particulars is similar to our own, and in principle is identical. All experts in preventive medicine have for some years seen that we cannot make the best of our powers over disease, and for the furtherance of health, until the laws and practices of all countries are similar in principle. England was the first to see the essential value of uniformity and to establish it by law in her own country. This undoubtedly redounds to our credit, but we must admit that the nature of our island, and the history of its constitutional system of government, rendered the establishment of a centralised co-ordinated public health service comparatively easy. In America such co-ordination is perhaps more difficult than anywhere else. This the association knows and recognises, but this difficulty has its compensations, for it enables the public health service to value itself. The first two paragraphs of the Declaration bring this out clearly:

The people of North America have for the past five years enjoyed a condition of good health not previously attained for any great population group of diverse races. This is not an accident of good fortune, nor an unearned asset of favourable climate or location.

The consistent continuous use of the medical and associated sciences through civil government is largely responsible for the present high level of health among the people of this continent, their entire freedom from certain pestilential diseases prevalent in former times, and the progressive reduction

in the spread of epidemic disease still commonly experienced.

This is interesting because it appeared about the same time that an eminent authority in England was questioning the essential values of our own public health service.

The American Association insists upon "a full-time trained health officer appointed on professional qualifications and secure against political interference or dismissal during competent performance." The reasons for this are the same as those held in England, not the least of which is that by full-time service alone can the medical officer of health act in concert with private practitioners and not in competition with them. We all know that the building up of a health service is an extremely complicated business, one full of traps in which all who have gone forward have fallen, and from which only those of superior courage or enlightenment have extricated themselves. We, who were first in the field and have generally kept in the van, have made the most mistakes, but whereas our own people are chiefly mindful of our falls, foreigners have been more interested in the ways we have recovered from them, so we can see the English system in its best light by studying the propositions of other countries.

Of the States of the American Union at the present day, many have, in whole or part, magnificent health services, but in others they are poor or hardly existent, and there is much lack of co-ordination. So, though localised epidemics are, in most American communes, worked out eminently satisfactorily both for science and for the protection of the people at risk, great epidemics or pandemics can only be solved in part and indifferently. The outlook for a unified highly efficient health service for the whole of the United States is much brighter today than it ever has been, for the political philosophy of the Americans is tending towards a more complete federation.

NEWS FROM THE FIELD

NATIONAL HOUSING ACT

DR. HAVEN EMERSON, Professor of Public Health at the College of Physicians and Surgeons of Columbia University and President of the American Public Health Association, issued a statement asking all public health officers and physicians generally to support the National Housing Act recommended to Congress by President Roosevelt. Dr. Emerson has been in close touch with the Administration at Washington regarding public health problems growing out of the depression.

As one professionally interested in what the National Housing Act will mean to the health and happiness of the American people, I am alarmed to learn that certain interests are attempting to prevent the passage of this bill at this session of Congress, or at least thoroughly to emasculate it. I am not competent to discuss the financial aspects of this bill and can only imagine that opposition to it might come from persons of the loan-shark turn of mind who would be likely to object to the elimination of a system anywhere under which a home owner would be likely to pay 35 per cent for second mortgage money, a state of affairs which I am authoritatively informed actually exists today in various parts of the United States.

What I am concerned with is the immediate benefits this bill will have if passed at this session of Congress upon the health and morale of the American people as a whole. Considering all sections, cities and towns and the rural districts, some housing conditions in both rural and urban America are but little better than those of the dark ages.

Here are some of the facts regarding American homes:

Even in the colder sections of the country a bare 33⅓ per cent, including apartments and tenements, have central heating. In the rural areas, which include towns of less than 10,000 population, only about one-sixth have plumbing in the house. Homes with running

water are less than one-quarter of the nation's total; homes with electricity are less than one-half. Many American homes, and by this I mean private, single dwellings, and not tenements, are nothing short of fire traps. Twenty-three per cent of all fires start on roofs, and as many as 75 per cent in rural districts. How many homes have fireproof roofs? The average American home is wasteful of heat in winter, because it is not properly insulated, and very uncomfortable in summer for the same reason. Kitchens and bathrooms are too often finished in wood, and hard to keep clean. Not only are there multitudes of homes lacking running water for bath and kitchen and toilet, but there are hundreds of thousands of homes where there is no privy of any kind indoors or out, and there are some thousands of school buildings in Southeastern United States lacking this elementary convenience so essential for health and prevention of communicable disease. Homes hardly more than shacks or shelters throughout the malarial areas of the South lack screens for doors and windows, upon which prevention of mosquito-borne infection depends. In many of our wealthiest cities the priceless privilege of direct and even indirect sunlight is denied to homes in the shadow of tall buildings. Without light the human being suffers as definitely as it does from infectious disease. It sometimes takes a depression or other disaster to make people realize how bad conditions are. In addition to putting some 500,000 to 1,000,000 men to work and removing immediate menaces to American health, I hope that the passage of this bill will awaken the American public to the fact that in housing on an average we are at least a century behind our present achievements in transportation and communication. I hope that health officers and physicians throughout the country will give their support actively to the National Housing Act.

It must be remembered that the National Housing Act is distinctly not a program of government spending. It does not call for a single home to be built or even repaired with government money. The National Housing Act will merely attract private capital into the neglected building field.

THE HOFFMAN LIBRARY FOR CANCER

THE gift of Dr. Frederick L. Hoffman's cancer library, made jointly by the Prudential Insurance Company and Dr. Hoffman, to the Cancer Research Laboratories of the University of Pennsylvania Graduate School of Medicine is a notable event in the medical history of Philadelphia.

The present Research Library of the Cancer Research Laboratories will eventually be combined with the Hoffman Library for Cancer to make a reference library for cancer which will be as unique as it will be valuable. The present Research Library was collected for special use in cancer research and contains 542 books, 459 bound volumes of journals and 7,309 classified reprints, with author and subject reference.

FOODS SPOILAGE BY BLUE LIGHT RAYS

RAYs of light at the blue end of the spectrum are responsible for much of the spoilage of foods commonly termed rancidity, reports Mayne R. Coe, a chemist in the U. S. Department of Agriculture. He states that chlorophyll green wrappers retard the development of this kind of spoilage almost as well as does the total exclusion of light.

CONGRESS OF PHYSICAL THERAPY

THE thirteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held in Philadelphia at the Bellevue Stratford, September 10-13, 1934.

For the preliminary program, address American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Ill.

NATIONAL CONGRESS OF PARENTS
AND TEACHERS

AT the 38th Annual Convention of the National Congress of Parents and Teachers held recently in Des

Moines, Ia., Mrs. B. F. Langworthy, of Winnetka, Ill., was elected President, and Mrs. J. K. Pettengill, of Lansing, Mich., was elected 1st Vice-President.

DEATH

GEORGE W. FULLER

GEORGE W. FULLER, of the firm of Fuller & McClintock, 11 Park Place, New York, died on June 15.

Mr. Fuller was President of the American Public Health Association 1928-1929; served on the Executive Board several times, and has been particularly active in the Public Health Engineering Section. He has been a Member since 1915 and was made a Charter Fellow in 1922.

PERSONALS

JAMES A. KENNEDY, M.D., F.A.P.H.A., has resigned as Professor of Bacteriology in the School of Medicine, University of Georgia, in order to accept the associate professorship in Bacteriology in the School of Medicine, University of Louisville, Louisville, Ky., and the directorship of the recently combined Bacteriological and Serological Laboratories of the Louisville City Hospital and Department of Health.

VICTOR MILDENBERG, M.D., Member A.P.H.A., has been appointed Acting Director of the Bureau of Preventable Diseases of the Department of Health of New York City by Commissioner John L. Rice, M.D.

S. BOUCHER, M.D., F.A.P.H.A., Director of Health of Montreal, Quebec, had the honorary degree of LL.D. conferred upon him by McGill University at recent graduation exercises.

THOMAS PARRAN, JR., M.D., Fellow A.P.H.A., New York State Commissioner of Health, received the degree of Doctor of Laws conferred

American Journal of Public Health and THE NATION'S HEALTH

Effect of a Confidential Inquiry on the Recorded Mortality from Syphilis and Alcoholism^{*}

A Survey in the Westchester County Health District

MATTHIAS NICOLL, JR., M.D., F.A.P.H.A.
AND MARJORIE T. BELLOWS

*Commissioner, and Statistician, Westchester County Department of Health,
White Plains, N. Y.*

AT a meeting of the Vital Statistics Section of the American Public Health Association in 1932, during a general discussion of the possibility of introducing a confidential form of death certificate in this country, the Westchester County Health District was suggested as a test area in which to try out some such system of reporting deaths. It was apparent that before any system could be introduced, a number of factors needed to be given careful consideration. In the first place, it was essential to determine the attitude of the medical profession toward such a project, not only whether it would cooperate but also if in this country it is reasonable to expect a physician to state the exact and complete cause of death on any official record if a part of the record reflects on the character

of the deceased. In addition to this, it was necessary to obtain some fairly accurate estimate of the extent to which certain diseases are underreported, in order to ascertain whether or not the present system of reporting causes of death is inaccurate enough to justify the effort and time involved in setting up a system of confidential reporting.

With these purposes in view it was decided to attempt a rapid survey in the Westchester County Health District to determine the extent to which alcoholism and syphilis had been underreported as causes of death during a 2 year period. These two causes were chosen, in spite of the fact that the number of deaths attributed to them is not a large proportion of the total mortality, because they are ones in which there is probably a significant amount of underreporting. The death certificates which had been filed with the County Department of Health during the 2 years from July 1, 1931, through June 30,

^{*} Read before the Vital Statistics Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

1933, were arranged and listed according to the name of the physician who signed them. The name, age, sex, date of death, and the primary and contributory causes of death which had been stated on the original death certificate were listed for each patient. Dr. William A. Holla, a physician and member of the staff of the County Health Department, who has long been a practising physician in the county, and who knows well the attitudes and problems of his professional confrères, visited each physician with the list of his deaths and asked him to state for each case—first, whether to his knowledge alcoholism or syphilis had been existent conditions at the time of death, and second, in the event that either condition had existed, whether, in the physician's opinion, it was a primary or contributing cause of death.

Alcoholism was defined for the purpose of the study as the habitual use of excessive amounts of alcoholic beverages. In order to assure the physician that no attempt was being made to use the data in such a way as to reveal his identity or that of his patients, the names of the decedents and the dates of death were detached and left with him. The sheet retained by the investigator and used in the following analysis shows only age, sex, originally assigned causes of death, and the newly acquired information.

Before beginning the survey, the proposed plan was outlined in detail to the Comitia Minora of the County Medical Society. This group not only heartily endorsed the project but volunteered to coöperate in every possible way. The president of the society sent a copy of a letter from the County Health Commissioner, which described the procedure to be followed, to every member of the Medical Society with his own letter of endorsement. As a result, the physicians showed the greatest coöperation and were extremely gener-

ous in giving time not only to furnish the desired information but to discuss the whole problem of confidential reporting and its advisability. Some of the local village and city medical societies coöperated by giving an opportunity at their meetings for an open discussion of the project. The results of the survey must, therefore, be considered as a coöperative effort on the part of the medical profession of Westchester County, especially the County Medical Society, and the County Health Department to obtain the most nearly accurate data possible.

The completed survey includes an investigation of 5,299 deaths. The certificates were signed by 365 physicians, each of whom was interviewed with the intention of finding out his reaction to the survey, whether or not he considers a confidential certificate practicable, and what system of reporting would be most satisfactory to him. These physicians comprise a representative professional group. The area in which they practise includes a population of 307,000 distributed in one city of 41,000 population, 5 villages over 10,000 population, 13 villages with from 2,500 to 10,000 population, and 17 rural townships. They included 3 physicians who reported the deaths which occurred in the county hospital, Grasslands, and the county medical examiner. The number of deaths occurring in their practices during the 2 years varied from 1 to 59 with the exception of the hospital physicians and the medical examiner, each of whom signed several hundred certificates.

One hundred and twenty-five of the group of 361 physicians who had deaths recorded among their private patients gave additional confidential information, when interviewed, which was not included on the official death certificate. Of these, 104 had not recorded either syphilis or alcoholism on any of their original certificates.

Although the physicians who gave additional data constituted only about one-third of the total number interviewed, they were those with the largest practices, and the certificates of death which they signed represented about two-thirds of the entire number recorded in private medical practice.

Practically all of the physicians agreed that it would be extremely valuable to devise a system of reporting whereby the exact cause of death could be stated without offense or detriment to the decedent, his family, and the attending physician. In most cases the reason for not stating all essential information relating to the cause of death seems to be that the certificate, before it finally reaches the record files of the State Department of Health, comes under the scrutiny of a local undertaker, a local registrar, his assistants, and other officials who may have access to such records. It is not unreasonable to suppose nor has experience failed to indicate that some of these persons have the human failings of curiosity and gossip. The fact that a death certificate is of access on legal order and that life insurance companies may demand a copy of the record for their purposes does not seem to be nearly so important a factor in promoting incorrect reporting as the element of local interest in fellow citizens.

It was the consensus of the medical profession that physicians would feel far freer to state the true cause of death if this information were sent directly to a central statistical office and did not go through the hands of local residents. Only 6 physicians, or 1.6 per cent, indicated that they disapprove of a confidential certificate, one of these giving as his reason that the present death certificate was adequate and not subject to any great amount of error if other physicians stated the cause or causes of death as accurately as he did. Several refused to discuss the project,

or felt that no system could be devised which would assure them that the data were confidential and would legally remain so under pressure of demands for information from sources which might have a legitimate interest in a specific case. The remainder expressed a definite desire to use a different system of reporting and all have shown an interest in the tentative results of the present survey, some suggesting even that other causes of death, such as cancer and tuberculosis, might have been included in this study to make it of maximum value.

The 5,299 deaths investigated fall automatically into 5 classifications with respect to authority for certification. The largest group, 3,583, were deaths of patients of private physicians practicing in the County Health District; 821 were deaths which occurred in the large county hospital, Grasslands; 621 were signed by the county medical examiner and for this group no additional information could be obtained; 228 were patients in a cancer hospital, Rosary Hill Home, where the certificates were all signed by one physician, in practically all cases the cause of death being cancer. This institution does not include in its records any extensive history of alcoholism and syphilis. Forty-six deaths occurred in Sing Sing Prison, the cause of death in all but 9 being legal electrocution. In the analysis of the effect of confidential reporting on the death rate, these 5 groups must be considered together. Throughout the study, however, the totals have been broken up into the component groups since the data so arranged give convincing evidence to substantiate the opinion that a large error is introduced solely by the physician's professional conviction that his first duty, even in matters involving official record, is to his patient.

Table I shows the actual increase in the number of deaths assigned to

TABLE I-a
DEATHS IN WHICH SYPHILIS* WAS
PRIMARY† CAUSE

* Includes syphilis, tabes dorsalis and general paralysis of the insane

† Classified as primary under rules of Manual of Joint Causes

‡ Includes medical examiner, cancer hospital, and Sing Sing Prison, from whom no additional information was obtained

** Includes alcoholism and alcoholic cirrhosis of the liver

of the physicians would have been recorded together with the additional information.

The number of deaths in the group in which syphilis, including tabes dorsalis and general paralysis of the insane, was a primary cause, increased from 40 to 79, a change of 97.5 per cent in the recorded death rate. Alcoholism or alcoholic cirrhosis of the liver was the original primary cause in 23 cases and the returns of the survey increased the figure to 44 or 57.1 per cent. It will be noted that the increase in the number of deaths from syphilis was considerably greater among physicians' private patients than among hospital patients, the only other group showing any change, and that all of the increase in deaths from alcoholism occurred among the former group. The number of males, among physicians' private patients, who died from syphilis increased from 17 to 33 (94 per cent) and the number of females from 8 to 20 (150 per cent).

The number of deaths from alcoholism and syphilis regularly reported from the hospital is proportionately much higher than in the rest of the county, and in the survey the number of cases in which additional information was obtained was considerably lower. The hospital has a very efficient pathologic service, performing autopsies on over 66 per cent of the deaths, and does not intentionally omit any facts regarding the cause of death on the certificate. The physicians there reviewed all of their cases for the purpose of the study although they felt certain that all essential data had been included on the death certificate. This procedure revealed, however, that syphilis had been omitted in 11 cases where, if it had been stated it would be assigned according to the *Manual of Joint Causes of Death* as the primary cause. In 3 instances the only cause given was aortic insufficiency or thoracic aneurysm, the im-

syphilis and alcoholism together with the percentage change which is also the percentage increase in the death rate. In arriving at these figures the most conservative method of assigning the cause of death was adopted. Only those cases in which the physician stated that syphilis or alcoholism was a primary or contributing cause of death were considered. These were coded according to the *Manual of Joint Causes of Death*, assuming that the original statements

plication of syphilis being so obvious in the mind of the physician that he assumed no further specification of syphilis as the cause was necessary. In the remaining 8 cases, other causes had been given and syphilis omitted even though it had been a definitely contributing factor, the omission being due largely to a tendency to take from the hospital record the final condition re-

sulting in death. These details are of value in showing the error which enters into certification in cases other than those involving personal relationships.

While the increase in the death rate measures the net statistical change resulting when additional data are secured, it does not show, especially in the case of alcoholism, the extent to which information is omitted from the death certificate. Table II shows for each disease the number of cases in which, according to the physician's statement, the cause should have appeared on the certificate and the number in which it was so certified originally. Syphilis as a primary or contributing cause was stated in 49.4 per cent of the cases in which it should have been, and alcoholism in 32.6 per cent. The amount of understatement among physicians' private patients (45.5 per cent of syphilis deaths and only 6.3 per cent of those from alcoholism were so classified on the original certificate) is a very significant element in determining the total figures.

It is of some interest to note the causes of death assigned by the physician in cases where these contributing factors were omitted. Table III shows the primary cause of death originally assigned in such instances. While certain of the leading causes of mortality (chronic nephritis, myocarditis, cerebral hemorrhage, and lobar pneumonia) were stated frequently, the numbers are so small that there would be no significant change in their death rates, even if all of the deaths were assigned to syphilis or alcoholism. The only causes (other than alcoholism and syphilis themselves) which were essentially changed by the facts obtained in the survey are non-alcoholic cirrhosis of the liver and aneurysm. Out of 30 deaths originally attributed to non-alcoholic cirrhosis of the liver, 10 in the physicians' opinion were due to chronic alcoholism and should have been as-

Influenza	2	43
All other causes†	8	4	5	1,344

* As either primary or secondary cause

† No specific cause appeared on more than one of the certificates on which syphilis or alcoholism should have been included in the statement of cause of death

signed to alcoholic cirrhosis of the liver, and 3 were due to syphilis. Out of 9 deaths in the entire group attributed by the original statements to aneurysm, 4 should have been assigned to syphilis.

The method followed in questioning the physicians has made available data which shows the incidence of alcoholism and syphilis among deaths. Table IV

gives the percentages of deaths in which each of these conditions existed for the 5 groups of patients. For the entire group, 1 in 30 males (3.3 per cent) and 1 in 49 females (2.0 per cent) were stated to have had syphilis at the time of death; 1 in 14 males (7.3 per cent) and 1 in 72 females (1.4 per cent) were stated to have been alcoholics.

SUMMARY

1. The great majority of the 365 physicians reporting deaths in the Westchester County Health District during a 2 year period feel that confidential reporting would result in far greater accuracy in the statement of causes of death than does the present official system.

2. Additional data secured confidentially by personal visit for 5,299 deaths resulted in a death rate from syphilis which is approximately double the recorded mortality and a corrected figure for alcoholism which is 57 per cent higher than the recorded rate.

3. Aneurysm and non-alcoholic cirrhosis of the liver were the only causes of death, other than syphilis and alcoholism, whose death rates were significantly changed by the survey data. The rates for these two causes were each reduced by somewhat more than 40 per cent.

4. Syphilis was stated on the original death certificate as a primary or contributory cause of death in approximately 49 per cent of cases in which it should have been so certified, and alcoholism in 33 per cent.

ACKNOWLEDGMENTS

We wish to express to the Westchester County Medical Society and to the individual practising physicians of the County our appreciation of the coöperation and aid which they have given and on which the entire success of the survey depended. This project was undertaken with the approval of the Council of the Vital Statistics Section of the American Public Health Association and to them we owe thanks for their advice and discussion.

Canadian Public Health Association

PUBLIC Health workers from all parts of the Dominion of Canada met in Montreal during the week of June 11 to attend the Annual Meeting of the Canadian Public Health Association, under the presidency of Dr. Alphonse Lessard, Director of the Quebec Provincial Bureau of Health. The total registration numbered nearly 400 members and guests.

As the Canadian Tuberculosis Association, with Dr. J. A. Couillard as President, was holding its annual meeting at the same time, the programs of the deliberations of the two organizations were arranged to permit several joint sessions.

The presence of Dr. Haven Emerson, President of the American Public Health Association, and of Dr. John A. Ferrell of the Rockefeller Foundation contributed to make the meeting one of

the most successful held in recent years.

A feature of the entertainment program was a dinner tendered by the Province of Quebec and the City of Montreal at which the Hon. A. David, Provincial Secretary, whose ministry includes the Bureau of Health, recounted the recent rapid progress effected in the public health of the Province of Quebec, and Dr. Haven Emerson conveyed to the Canadian Associations the greetings of the American Public Health Association.

The Canadian Tuberculosis Association reëlected Dr. J. A. Couillard for President, for the ensuing year. The new President of the Canadian Public Health Association is Dr. F. W. Jackson, of Winnipeg. Dr. Alphonse Lessard, retiring President, was elected an Honorary President of the Association.

A Study of Granite Cutting and Granite Cutters in the Vicinity of New York City

ADELAIDE ROSS SMITH, M.D., F.A.P.H.A.

Division of Industrial Hygiene, New York State Labor Department; Associate in Medicine in Industrial Hygiene, College of Physicians and Surgeons, New York, N. Y.

THIS was a study of 125 men employed in stone yards in and about Greater New York undertaken to determine the extent to which silicosis is present among them. Since the total number of granite cutters in the state is estimated at about 2,000 this represents approximately 6 per cent. This industry in general presents a serious silicosis risk * but, so far, disappointingly little progress has been made in its control. It was thought that any additional evidence of the need for such control which such a study might furnish would be of value in stimulating preventive action. Examination of the men was supplemented with comprehensive dust counts in two representative yards.

The study was a coöperative undertaking on the part of the Division of Industrial Hygiene of the New York State Labor Department, the New York Tuberculosis and Health Association, and the Industrial Health Department of the Metropolitan Life Insurance Company, together with a group of

stone yard employers and the local branch of the Granite Cutters International Association. Dr. J. Burns Amberson of the Tuberculosis Service, Bellevue Hospital, read the X-ray films.

GENERAL DESCRIPTION OF THE INDUSTRY

Stone cutting in and about New York City is carried on in some 200 plants, most of them small, employing on an average less than a dozen men each. In normal times work is steady and the men are busy throughout the year. The work is done partially in the open, the sheds as a rule being open on at least one side. Conditions of work thus differ from those in some other states where, on account of more severe winter weather, work is carried on for the most part in enclosed sheds. This difference has been considered by not a few employers about New York City a basis for the belief that stone cutting in this vicinity is less harmful than it is known to be in New England.

All of the men examined worked with granite which because of its durability has to a large extent replaced softer stones such as marble, limestone, and brown stone, for monumental and building purposes. Granite used in New York is shipped from quarries in New England and the West. Its free silica content ranges from about 25 to 35 per cent. It is received in rough blocks

* Studies made by the Public Health Service in Barre, Vt., in 1924-1926 showed that practically all the granite workers had well advanced silicosis after 10 years, while the death rate among them for tuberculosis alone exceeded the death rate for all causes in the general population. Previously, in 1922, Hoffman had emphatically called attention to the high death rates in the industry and commended it particularly to consideration on the part of the state, the medical profession and the labor organizations directly concerned.

Surfacing machine in operation. See dust sample No. 8, Plant A.

which are cut when necessary to the desired size on circular saws using steel grit and water. Carborundum saws with water may be used for trimming. After this preliminary treatment the blocks are suitably finished according to their purpose and destination and it is in the process of producing finishes of various kinds that the dust hazard in this industry occurs.

Finishing is done by surfacing machines and hand pneumatic tools which, about 30 years ago, began to replace the old time hammer and chisel. The surfacing machines are used for large plain surfaces where no design or edging is required. They are essentially pneumatic hammers, the particular size and shape of hammer desired being fitted into a movable arm with a piston operated at the rate of some 5,000 blows per minute. The operation is dry and the amount of dust produced is great, sometimes sufficient to envelop the operator completely.

The hand machines also are operated

by compressed air. The machine is held in the operator's hand and with his face 12 to 18 inches away he guides it over the surface of the stone. Chisels of various sizes are the tools most commonly used in the hand machines. The amount of dust produced by them is considerable and, owing to the proximity of the operator's face, he gets its full effect. In addition to the dust created in operation, operators add materially to the hazard themselves by blowing off dust which has accumulated on the surface of the stone with the exhaust from their tools.

Polishing is usually done with polishing machines using shot, carborundum grains, or felt with water and is not a dusty process. Sometimes, however, small carborundum wheels are attached to the hand tools for polishing smaller stones. This operation is extremely dusty, and wetting the stone which is sometimes resorted to, is entirely ineffective in allaying the dust.

In addition to surfacing, finishing,

and polishing, lettering by means of sandblasting is done in almost all stone yards. A sandblast cabinet is required for the work, but owing to improper maintenance, dust may be found escaping in large quantities and adding to the hazard of those working in the vicinity.

DUST COUNTS IN TWO REPRESENTATIVE YARDS

Studies of the dustiness of representative operations were made in two typical yards, A and B, by W. J. Fehnel of the Industrial Health Department of the Metropolitan Life Insurance Company. The results are given in Tables I and II. The dust sampling and counting were done according to

the standard technic of the U. S. Public Health Service, using the Greenburg-Smith Impinger. Particle size measurements of the dust were made by making micro-photographs under a high dry magnification and further enlarging the negatives by projection. It has been demonstrated repeatedly that no silica particles exceeding 10 microns in greatest diameter enter the lung tissue, and for this reason it is the general practice to consider as hazardous only dust particles under 10 microns. A micron equals one-millionth part of a meter or one-thousandth part of a millimeter. From 98.60 to 99.95 per cent of the particles were found to be less than 10 microns in their greatest diameter.

In the investigation of granite cutting

plants conducted by the U. S. Public Health Service at Barre,¹ it was found that under conditions pertaining there with granite dust containing 35 per cent of free silica, a safe limit of between 9 and 20 million particles of dust, less than 10 microns in longest diameter, per cu. ft. of air could be established. Workers exposed to this degree of dustiness did not appear to show any increase of respiratory disease. Since at the time of the survey of Plant A only granite was being worked, these findings are directly comparable with those of the Barre study.

It can be seen that the only operations where the dust counts could be considered within the limits of safety were those of gang sawing and polishing, both wet operations. The conspicuously high counts at the surfacing machines were due to the lack of any exhaust devices. These machines at one time had been equipped with exhaust hoods and dust collecting apparatus, but the system had not been operated for some time.

The sandblast cabinet permitted considerable seepage from various small openings at the curtains and around the windows. Dust thus escaping exposed not only the operator but other workmen in the vicinity to high dust concentrations.

It will be noted that the dust counts were considerably lower in Plant B than Plant A. This is attributed to the weather conditions at the time of the tests. Plant A was examined on a clear dry day; Plant B on a damp day with a fine mist in the air. However, in Plant B also the only safe operations were those conducted with water, namely polishing and sawing.

In this plant the six surfacing machines were equipped with individual exhaust systems augmented by directing the exhaust from the tool into the exhaust hood placed at a level with the point of dust generation. The prac-

tice was to discharge the collected dust into a wooden chamber where the heavier dust settled out and the fine, lighter dust was discharged directly into the atmosphere outside the shed. When the wind blew in certain directions this fine lighter dust was blown back into the breathing zone of the workmen at the various operations in the plant.

Sandblasting in this plant was done in two sand blast cabinets but the curtain and screening did not provide an efficient seal against the escape of fine dust, nor were the cyclone separators, used to entrap the dust exhausted from the sand blast cabinets, efficient in entrapping the fine particles.

The particle size distribution studies made in Plant A, showed that more than 90 per cent of particles were 5 microns or less in size in all operations studied but two. In plant B, on the other hand, the number of particles of 5 microns or less in size averaged 75.5 per cent. This tendency to a slightly higher particle size in plant B was also, in all probability, the result of differences in weather conditions at the time tests in the two plants were taken.

EXAMINATION OF MEN

The coöperation of the stone cutters themselves in examinations was secured by explaining the purpose of the study to the men at their union meetings, and those examined represented a purely voluntary group who were accepted as they came without discrimination as to age, length of service or any other consideration.* Each man was interviewed before his examination and a personal and occupational history was taken. The occupational history covered the place and type of work, the number of years engaged in it, the use of pneu-

* The examinations were conducted at the Bellevue Yorkville Clinic through the courtesy of Dr. Margaret Barnard. Dr. Leonard Goldwater, Chief of the Occupational Disease Clinic of New York University and Bellevue Hospital Medical College, kindly lent his assistance.

matic tools, and the presence of ventilating devices. The personal history included a record of age, birth place, past diseases referable to the respiratory tract, of contacts with persons suffering from tuberculosis, and of the presence and details of symptoms associated with respiratory disease.

After the history taking each man received an X-ray examination of his chest. Two exposures were made in each case for spectroscopic examination. The technic was as follows: distance 48 inches, length of exposure $1/10$ seconds, milliamperes 100, voltage varied according to chest thickness.

The physical examination included a record of height, weight, vital capacity, and chest expansion; observation on the presence of clubbing or cyanosis and a physical examination of the chest. Specimens of sputum were sent for examination to the City Board of Health Laboratories in 34 cases. Complete blood counts were made in 20 cases, at the New York State Health Department Laboratories.

In a number of cases where the X-ray examination showed evidence suggestive of tuberculosis which was not confirmed by physical examination or laboratory findings, it was felt that further observation was desirable, and an effort was made to get these men to enter Bellevue Hospital. The effort met with little success, however, since the men did not wish to take time away from work, and less than half a dozen complied. Since the study was made, 2 have been placed under treatment in tuberculosis sanatoria and 1 has died.

CHARACTERISTICS OF GROUP EXAMINED

Nationality—The distribution of the group by nationality is shown below. Italians strongly predominated, constituting 40 per cent of the total. The United States, Sweden, Scotland, Germany, and Ireland furnished another 45 per cent, and the remainder came

from a dozen different countries of Europe and South America.

NATIONALITY OF MEN EXAMINED

<i>Country of Birth</i>	<i>Number</i>	<i>Per Cent</i>
Italy	50	40
United States	16	13
Sweden	14	11
Scotland	11	9
Germany	8	6
Ireland	8	6
Spain	4	3
South America	2	2
Hungary	2	2
Finland	2	2
Other countries	8	6
TOTAL	125	100

Occupation—The occupational classification of workers in these small yards cannot be clear-cut because there is always a good deal of shifting about. Most of the men called themselves cutters, but a cutter may at times operate the surfacing machine or do sandblasting or *vice versa*. Subject to this qualification the occupational distribution is given below.

OCCUPATION OF MEN EXAMINED

<i>Occupation</i>	<i>Number</i>	<i>Per Cent</i>
Cutter	111	88
Sand blaster	6	5
Polisher	4	3
Surfacer	2	2
Sawyer	1	1
Blacksmith	1	1
TOTAL	125	100

All of the cutters with the exception of one reported the use of pneumatic tools for cutting most of the time, and half of them had never done any cutting by hand. Any hand work had been carried on as a rule in the old country before coming to America. About 10 per cent of the men had cut stone exclusively in New York State, the remainder had spent varying amounts of time in stone yards elsewhere, chiefly in New England and the Middle West. The place of work, how-

ever, would seem to have little bearing upon the incidence of silicosis, since the studies of dust concentrations in New York City yards show them to be entirely adequate to produce the disease.

In the experience of these men ventilating devices for hand pneumatic tools were practically nonexistent. Only one cutter reported any exhaust for this type of work. In several instances lack of exhaust ventilation for machine surfacing was mentioned. The use of masks was reported by only two cutters who wore them on their own initiative.

Results of X-ray Examination—Interpretation of the X-ray appearances in this study followed in general the classification suggested by the Silicosis Committee of the American Public Health Association in which first stage appearances are described as generalized arborization throughout both lung fields with more or less small discrete mottling; second stage appearances as generalized medium sized mottling through both lung fields, and third stage appearances as more intense mot-

tling with larger nodules taking on a conglomerate form so that large shadows are shown corresponding to areas of dense fibrosis.

There is always a question as to whether a marked generalized increase in fibrosis without mottling may be indicative of silicosis also. In the classification of silicosis suggested by Pancoast and Pendergrass² a non-nodular type of fibrosis occurring in silicosis is recognized. Thompson³ in his report on silicosis among granite cutters in Barre, Vt., says that mottling was conspicuous by its absence. However, lacking antecedent X-rays to show the development of fibrosis in a previously normal lung after exposure to rock dust, it seems better not to consider cases without at least some nodular fibrosis as silicosis because of the frequency with which generalized fibrosis occurs in lungs when there has been no dust exposure.

The X-ray examination of these men yielded results which are shown graphically in Figure I.

Eleven cases, or 9 per cent, showed

FIGURE I
X-RAY FINDINGS IN GROUP OF 125 GRANITE CUTTERS

essentially negative lungs. In 22 cases or 18 per cent of the total, increased fibrosis was noted. In 13 cases, or 10 per cent, there was increased fibrosis with a question as to whether or not it represented beginning silicosis. Thirty cases, or 24 per cent, showed silicosis in an early stage. Sixteen cases, or 13 per cent, showed second stage silicosis. There was 1 case of simple third stage silicosis, and 1 of apparently early uncomplicated tuberculosis.

TUBERCULOSIS AND SILICOSIS

There were 31 cases or 25 per cent of the total in which signs suggestive of tuberculosis with silicosis were found. In 13 of these the signs were considered to constitute definite evidence of tuberculosis. In 11 the signs were thought to indicate probable and in 7 possible tuberculosis where further study would be necessary for a definite diagnosis.

The silicosis in this group of 31 appeared to be advanced in three-fourths of the cases. The tuberculosis found was uniformly of the chronic fibroid type affecting the apices in every case and involving the bases also in only 4. Definite cavity formation was found in 5 instances. In another 7, small areas of rarefaction were present which may have represented either cavity formation or bullous emphysema.

This apical type of tuberculosis with silicosis is considered by Gardner from his studies of silicotic lungs to represent an early focus which has been re-activated or not permitted to heal under the influence of dust, rather than a new infection occurring at the time of dust inhalation. From the number of apparently latent cases and the relatively good condition of many of those with definite signs, the infection was shown to be mild even if widespread. The type of tuberculosis reported as constituting an outstanding group among the Barre granite cutters, namely that with a sudden onset, rapid course, and predominatingly basal lesions, was not found in this study.

The extent to which tuberculosis figures as a cause of death among granite cutters in this state can be seen from Table III where a comparison is shown of the tuberculosis mortality rates among granite cutters and all adult males in New York for the years 1928 to 1932.

In the tables which follow the total group is presented in sub-division according to the X-ray findings. In the sixth group, "tuberculosis and silicosis," all cases showing either definite, probable, or possible evidence of tuberculosis are included.

Age.—The distribution of the group

TABLE III

according to age and the relation between age and X-ray findings is shown in Table IV.

The average age in the negative group was 30 years. In the "increased fibrosis," "questionable silicosis," and "first stage silicosis" groups it ranged in the vicinity of 41 years; in the group showing second stage silicosis it was

57, and in the group with evidence of tuberculosis and silicosis it was 50 years.

Length of Exposure to Dust—Three of the men examined had been exposed under 5 years; these cases fell in the "negative" and "increased fibrosis" groups. Three had been exposed over 50 years; these cases fell in the "second stage" and "tuberculosis with

60-69						1 3	1 1

FIGURE II
X-RAY FINDINGS IN RELATION TO LENGTH OF EXPOSURE

silicosis" groups, as will be seen from Table V. Among the cases showing first stage silicosis, more fell in the 20 to 29 year exposure group than any other, though 2 had been exposed less than 10 years. Among the cases with second stage silicosis more fell in the 30 to 39 year exposure group than in any other. Among those with silicosis and tuberculosis the majority had been exposed from 20 to 39 years. The cases showing "questionable silicosis" were equally distributed over all exposure groups from 5 to 39 years.

The picture given is one of a slowly developing type of silicosis which may show its first stages after anywhere between 5 and 40 years, and tends to become advanced with a marked tendency to be complicated with tuberculosis after 20 years' exposure.

Past History—The history of past respiratory disease revealed a slightly greater frequency of influenza and bronchitis in the group with signs suggestive of tuberculosis and silicosis. This group and the one with second stage silicosis also reported pleurisy with greater frequency than the other groups.

Known contacts with cases of tuberculosis were reported by 4 men, 18 per cent, whose X-rays showed fibrosis; 3, 10 per cent, of those showing first stage silicosis; 1 showing second stage silicosis, and 2, 6 per cent, with evidence of tuberculosis and silicosis.

So far as symptoms and physical signs are concerned this study contributed little to what has been found repeatedly in other similar investigations, unless it be to reemphasize the paucity of both.

Symptoms—Dyspnea was the only symptom clearly related to silicosis. It was reported by 50 per cent of those showing second stage silicosis as compared with 9 per cent in the negative group. Three men were incapacitated for work by it at or shortly after the time of examination. Cough and expectoration were reported with as much frequency by those with increased fibrosis as by those with more advanced changes. Hemoptysis was reported in 3 cases where there was evidence of tuberculosis and 1 case showing increased fibrosis. Six cases out of 17, 37 per cent, with X-ray evidence of second stage silicosis, and 13 out of 31,

42 per cent, with evidence of tuberculosis and silicosis complained of no respiratory symptoms whatever.

Appearance—With very few exceptions the men were of robust appearance and very well nourished. Overweight was the rule except in the group showing evidence of tuberculosis. In this the average weight for the group approximated the standard for its age and height. Build tended distinctly toward the short and stocky as can be seen from the average heights and weights given in Table VI. The same table shows the average actual vital capacity for each group and the average per cent of normal calculated on the basis of height.

Vital Capacity—In general, the per cent of normal vital capacity diminished with the increase in fibrosis, but in each group there were marked individual variations, dependent to some extent doubtless on degree of coöperation or on practice. Table VII gives the vital capacities and percentages of normal for 123 individuals arranged by X-ray groups.

In the negative group there were none whose vital capacity was less than 75 per cent of the calculated normal. In the group showing increased fibrosis 14 per cent had vital capacities 75 per cent or less of normal; in the "questionable silicosis" group there were 38 per cent with this degree of limitation; in the "first stage silicosis" group 20 per cent; in the "second stage silicosis" group 32 per cent. No relationship was found between subjective dyspnea and diminished vital capacity.

Chest Expansion—Chest expansion in all groups, including the negative, was less than normal. It averaged 6 cm. for this group, 5 cm. for those with first stage silicosis, and 4 cm. for those with second stage silicosis and silicosis with tuberculosis. The limitation of expansion was doubtless related to the

predominating broad-chested type as well as to fibrosis.

Clubbing—Clubbing of the fingers or definitely curved nails were found in one-half of the cases with evidence of tuberculosis and silicosis in contrast to 9 per cent in the negative group and 18 per cent in the group with second stage changes.

Lung Findings—Lung findings were variable and not of material aid in making a diagnosis of silicosis. Negative lungs were reported in approximately one-third of the cases showing second stage silicosis by X-ray. The presence of emphysema in many cases masked evidence of other changes. In 7 of the 31 with suggestive evidence of tuberculosis by X-ray, persistent râles were noted. Altogether clinical corroboration of the presence of tuberculosis by symptoms and physical signs was found in 12 of the 31 suspected cases.

Blood Counts—Complete blood counts were made in 20 cases including both silicotic and non-silicotic individuals, but did not show any significant variations from normal, and the average red blood cell count, white blood cell count, percentage hemoglobin, polymorphonuclears and lymphocytes were almost identical in all groups.

Sputum—Of the 34 specimens of sputum examined 2 were positive. Fifteen of the 34 came from the group suspected of tuberculosis. It seems quite possible that a higher proportion of positives would follow repeated examinations of concentrated specimens.

SUMMARY

Studies made in two representative stone yards showed that dust counts exceeded limits of safety in all operations except machine polishing and sawing.

Examination of 125 granite cutters revealed evidence of silicosis in 78 cases, or 62 per cent, of the group examined. In 41 cases, or 33 per cent,

the condition was advanced. In 12 cases, or 10 per cent, there was definite evidence of tuberculosis also, and in 19 cases, or 62 per cent, of the group ex- others, 15 per cent, it was suspected.

The study shows that the dust hazard in granite cutting shops about New York City is not controlled, and that the men are subjected in the course of their daily work to conditions which are so damaging to health as to demand immediate correction.

POSSIBILITIES OF CONTROL

There is no doubt that the serious hazard existing in stone yards can be controlled if there is a will to control it. The methods of control are the well known ones of local exhaust ventilation, direct protection of the workers by masks, and good housekeeping. The will to employ these methods must be aroused by education, and reinforced when necessary by law.

Exhaust Ventilation—Equipment can be and has been designed to remove dust from the point of origin in stone yards which is efficient and durable. The U. S. Public Health Service published *A Study of the Efficiency of Dust Removal Systems in Granite-Cutting Plants in Public Health Reports*, October 18, 1929, in which it was found as a result of a careful study of exhaust ventilation in two yards that in most instances it was possible to keep the dust concentration in the air of the sheds below 10 million particles per cu. ft. Exhaust for both surfacing machines and hand pneumatic tools is described.

Hatch, Drinker, and Choate in *A Laboratory Study of the Design of Dust Control Systems for Use with Pneumatic Granite Cutting Tools* appearing in the *Journal of Industrial Hygiene*, March, 1930, described the construction of devices for dust control in the use of pneumatic hand tools and surfacing machines which will maintain a maxi-

mum dust concentration of 10 million particles per cu. ft. Since the publication of the above article, one of the authors has installed a system which has demonstrated over a period of time its ability to maintain low dust concentrations in a large stone yard which is entirely enclosed.

The cost of such equipment is not prohibitive and its principles do not differ from the well known ones of exhaust ventilation wherever applied. It is true that a certain amount of intelligent coöperation on the part of the worker is necessary for securing best results, but this is not by any means impossible of achievement where the employer himself is interested and alert.

Masks—Where exhaust ventilating equipment is not installed, an alternative is direct protection of workers by the use of masks. Positive pressure masks or helmets supplying the wearer with clean air from an outside source are to be preferred wherever they are practicable, that is to say, where the worker's radius of movement is not over 10 feet. Operators on sandblasting and large surfacing machines could very well be so protected. For other workers who may be moving from place to place simple filter masks are recommended.

The Bureau of Mines' study, *Dust Respirators, Their Construction and Filtering Efficiency** shows that an efficient filter for dust particles, even those as small as 0.27 microns in diameter, can be made from a sufficient number of plies of muslin, cotton flannel, cheese cloth, or absorbent cotton, and a number of satisfactory respirators using this principle are obtainable in the market. When masks are used, one man must be assigned to the duty of distributing, collecting, cleaning, replenishing and generally keeping them in good condition; otherwise carelessness in their use and a false sense of protection will result.

* *Technical Paper 394.*

Good Housekeeping—Next to exhaust ventilation and direct protection by masks, good housekeeping plays an essential part in control of the dust hazard. Under this heading is included proper maintenance of equipment and the avoidance of any unnecessary dust exposure which might result from ill considered arrangements. An example of the latter found in one of the yards investigated, for instance, was the reconditioning of sand by screening which took place adjacent to the sandblast cabinet in a position which exposed a number of nearby workers to the dust so created. Poor maintenance, lack of good housekeeping was responsible for the fact that sandblast cabinets leaked and dust exhausted from the surfacing machines blew back under certain conditions into the yard. Again, as in the case of care of masks, attention to such details must be the business of somebody who understands the hazard and *wants* to control it.

Legislation—To create the will to control the hazard, continuous persistent dissemination of information is necessary, plus the stimulus of vigorously administered law. In New York State there is a Code of the Labor Department¹ having, as do all such codes, the force of law which specifies "Every granite working tool or machine shall be connected to an exhaust system including a separator that will remove all dust created by such machines or tools, in so far as it is practicable, at its point of origin."

The value of such a code strictly enforced is apparent. The trouble has

been in New York State in the past that the seriousness of the hazard has not been thoroughly appreciated and observance of the Code has not been insisted upon.

Finally, the most important factor of all in stimulating the institution of preventive measures in this or any industry with a similar hazard would be the inclusion of silicosis in the Workmen's Compensation Law. To achieve this end, those who are interested in silicosis prevention should bend every effort.

Diphtheria Studies:

1. The Significance of the Schick Test in the Adult*

C. C. YOUNG, D.P.H., F.A.P.H.A., W. E. BUNNEY, Ph.D., MINNA CROOKS, G. D. CUMMINGS, Ph.D., AND F. C. FORSBECK, M.D.

Michigan Department of Health, Lansing, Mich.

OUR knowledge of the Schick test is limited almost entirely to data on the reaction in children. Little study has been made of the reaction in adults, especially older adults. Knowledge of the significance of the test in this group is of practical importance to the authorities responsible for immunization in institutions for adults. Furthermore, a detailed knowledge of the Schick reaction in relation to age would add to our understanding of the immunology of diphtheria.

There are indications that immunity to diphtheria in adults depends in part upon some factor not measured by the Schick test. Since the decrease of diphtheria with age is more rapid than would be expected from a knowledge of Schick reaction distribution in adults, it seemed possible that a comparison of blood antitoxin concentrations with Schick reactions might throw light on this discrepancy. We also desired information on the following points:

1. The level of antitoxin at which all adult Schick reactions are negative, and below which all are positive.

2. The immunologic significance of the pseudo and combined reactions, and of the type of tissue reaction (necrosis, vesiculation, pigmentation and erythema).

3. The relationship between the Schick reaction and antitoxin concentration in adults artificially immunized, as contrasted with adults naturally immunized.

4. The relationship of age to the correlation between antitoxin, Schick reaction, and tissue reaction, both before and after antigenic stimulation.

In children there is probably no antitoxin concentration (as determinable by available methods) below which all are positive to the Schick test, though as Dudley¹ points out in his critical review of the literature on the Schick test, most authors accept Schick's original figure of 0.033 unit as the "threshold." The results of Ramon and Debré² agreed with those of Schick. However, other critical levels are reported. In 1923, the Medical Research Council of Great Britain³ considered 0.025 to 0.017 unit as the dividing range. Schick⁴ in 1924 indicated that 0.005 unit was sufficient to render an individual Schick negative. Kellogg and Stevens⁵ found that 20 to 25 per cent of those receiving toxin-antitoxin became Schick negative with a final antitoxin level of less than 0.01 unit. Jensen⁶ believes that the Schick reaction does not divide children into high and low antitoxin groups which are mutually exclusive. He found that 9 per cent of the negatives, after antigenic stimulation of a group of positive children, had less than 0.01 unit, but

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 9, 1933.

that 100 per cent of the positives had less than 0.003 unit. Flood believes that a positive Schick test always indicates susceptibility, but that a negative may or may not indicate immunity. Schick, Von Groer and Kassovitz⁸ found that 0.002 unit always gave a negative Schick and 0.005 always a positive. Kolmer and Moshage⁹ found it required at least 0.05 unit for a person to become Schick negative. Peckels¹⁰ found negative Schicks with less than 0.01 unit. Thiele¹¹ found that of 132 negatives 22 per cent had less than 0.05 unit of antitoxin. Curth and Lorenz¹² found that all Schick positive children had less than 0.04 unit, but that of 25 Schick negative children, 7 had less than 0.01 unit. Henseval and Clevers¹³ found that guinea pigs were negative to the Schick test when there was 0.005 unit, and positive when there was 0.0033 unit. Weichsel¹⁴ found that guinea pigs having 0.01 unit or more had negative Schick reactions. All with less than 0.01 unit were positive. He found that resistance to conjunctival infection with an old laboratory strain of *C. diphtheriae* correlated with the Schick reaction. However, resistance to conjunctival infection with a highly virulent strain occurred only when the pigs were negative to 1/25 of an m.l.d. instead of the 1/50 m.l.d. used in the Schick test, and when the antitoxin concentration was from 0.03 to 0.05 of a unit of antitoxin. Complete resistance to the infection was obtained only if the pigs were negative to 1/10 m.l.d.

Evidence has been submitted by several workers listed above to show that persons with negative Schick reactions, and as little as 0.01 unit of antitoxin, are not uncommon. In view of this the following gains in interest: That Park¹⁵ stated in 1926 that he had never seen an undoubted case of clinical diphtheria in a child who had recently had a negative Schick; that O'Brien, Okell,

and Parish¹⁶ observed only 18 frank but mild cases in 20,000 Schick negative persons; and that Lane and Forsbeck¹⁷ and Lane¹⁸ reported that of the 263 diphtheria deaths investigated in Massachusetts in 1926 and 1927, none occurred in Schick negative persons.

One is led to conclude that the negative test may sometimes indicate a non-antitoxic immunity, or an immunity which is not represented merely by the concentration of antitoxin in the blood stream. On the other hand, there is a widespread belief that with increasing age a positive Schick reaction has less and less significance as an indication of susceptibility.

Likewise the work of Von Groer and Kassowitz,¹⁹ Kuttner and Ratner,²⁰ Ruh and McClelland,²¹ and Cooke and Sharma²² demonstrating that the positive Schick reaction in a newly-born infant is often smaller and less intense than in the mother with the same concentration of antitoxin, seems to indicate that the Schick reaction may be influenced by factors other than the blood antitoxin concentration at the time of the test.

It seemed to us that a simultaneous determination of antitoxin concentrations and Schick reactions in the adult might throw further light on this problem.

METHODS

FIELD TECHNIC

All observations were on male adult patients in two Michigan hospitals for the insane.* Data from the two hospitals were routinely compared and found to be essentially similar. Blood was drawn not more than 24 hours before doing the Schick test. At first,

* We are indebted to Dr. Edmund A. Christian, Medical Superintendent of Pontiac State Hospital, and to Dr. R. Phillip Sheets, Medical Superintendent of Traverse City State Hospital, for their cooperation and assistance.

bloods were drawn with sterile dry syringes and transferred to vials which were then stoppered and refrigerated. Later, bloods were drawn directly into vials with suction apparatus.²³ This expedited the collection of blood and reduced contaminations. Schick reactions were read on the 4th and 6th day at one hospital, and on the 5th and 7th day at the other. Since analysis showed no significant differences, the 5th day reading in one hospital and the 6th day reading in the other were selected for this paper. Schick tests were done on the left forearm, controls on the right. Reactions were read by any one or more of the group after it was found that all members agreed as to interpretation of kind, size, intensity, and other characteristics.

Kind of Schick test as used in this article refers to the classification of reactions into negative, pseudo, combined, and positive. The reactions as to size were divided into 5 groups as follows:

Group	Diameter in Millimeters
1	0-9
2	10-19
3	20-34
4	35-44
5	45+

The complete Schick reading was represented by two numbers, the first giving the size of the control, the second the size of the test. Below are listed the symbols of the 15 possible readings excepting those occasional irregular readings in which the control reaction was larger than the test.

Negative	Pseudo	Positive	Combined
11	22	12	23
	33	13	24
	44	14	25
	55	15	34
			35
			45

Thus, a given symbol tells at once the kind of reaction as well as the approximate size of both the test and control reactions. After a few readings the

group was able to agree as to the correct symbol to assign. Naturally, if the size were 20 or very close to 20 mm. the symbol assigned by two observers might be "2" in one case, and "3" in the other. Furthermore, there were a few border-line reactions which required common sense interpretation, such as follows:

Control	Test	Interpretation
0 mm.	9 mm.	Positive rather than negative
19 mm.	21 mm.	Pseudo rather than combined
20 mm. faint reaction	20 mm. intense reaction	Combined rather than pseudo

The color of the Schick reaction was recorded as follows:

1. Flushing, a pink which disappears with pressure
2. Red, the red of the typical Schick reaction
3. Bright red, the "angry" red associated with inflammation
4. Purple, perhaps a reaction to trauma
5. Brown, the brown of pigmentation

In addition, vesiculation, induration, necrosis, swelling, and desquamation were recorded. Reactions occurring as two-shade zones were also recorded.

One, two, or three subcutaneous injections of toxoid were made at the time of Schick readings and thereafter at 3 week intervals. The post-antigenic stimulation Schicks were done 3½ months after the first toxoid inoculation at one hospital and 7½ months after the first toxoid inoculation at the other. Contaminated specimens were discarded. Sera were not separated from their blood clots at uniform intervals after procurement. Antitoxin titrations were made* according to Fraser's²⁴ modification of Römer's technic. Guinea pigs were used for test animals. Twenty inoculations were made on each pig.

* We wish to acknowledge the assistance of J. W. Glasen, H. C. Hollon, H. Kibbe and A. H. Tallman.

* The antitoxin concentrations of less than 0.002 units per c.c. of serum have for the purposes of analysis been assumed to average 0.001. Actually the relatively large number of antitoxin titrations below 0.002 point to a much lower average.

The pre-antigenic stimulation sera were titrated to 0.1 unit per c.c. Since 43 per cent of sera contained more than this amount of antitoxin the post-antigenic stimulation sera were titrated to 7.5 units. Levels for titration were chosen to include the various "Schick levels of antitoxin" reported by other workers. But examination of our results shows that for determining the distribution of antitoxin concentrations it would have been better to have covered a greater range. Limitations of the methods for antitoxin titrations however make determinations below 0.002 of doubtful value.

RESULTS AND DISCUSSION — SCHICK TEST AND ANTITOXIN CONCENTRATION

In Table I are listed the number of persons at each antitoxin level and in

each Schick group previous to antigenic stimulation.* The percentage distribution of Schick reactions by antitoxin levels is presented, as well as the percentage distribution of antitoxin levels by kind of Schick reaction. As expected, the positive reactions are mostly at lower antitoxin levels, and most of the negative reactions at upper levels. With enough figures to be significant we find that with each increase in the antitoxin concentration the percentage of negatives increases. Thus at 0.001,† 6.1 per cent of the Schick reactions are negative, at 0.002, 38.8 per cent are negative, and at 0.006, 76.4 per cent are negative. From this point on there is no significant change. If however the percentage of pseudos is added to the negatives, we find a continued trend toward 100 per cent immunity as measured by the Schick test. The percentage of pseudos also increases with

* Throughout this paper antigenic stimulation refers to artificial stimulation with toxoid or with Schick test material.

† Figures representing antitoxin concentrations always refer to units per c.c. of serum.

each increase in antitoxin concentration, but our figures are too few to determine whether the percentage of pseudos tends to increase at a faster or slower rate than the percentage of negatives.

In Table II is shown the relationship between the Schick reaction and antitoxin concentration after antigenic stimulation of Schick positive persons. It may be noted that whereas there is

considerable scatter of the positives over the antitoxin range before antigenic stimulation, the positives are more concentrated at the low antitoxin levels after stimulation. With one exception, no positive had more than 0.01 unit after antigenic stimulation.

These data are summarized in Table III in such a way as to show the discrepancies. Perhaps the figures point

TABLE III
THE DISCREPANCY BETWEEN THE SCHICK REACTION AND ANTITOXIN CONCENTRATION
IF 0.03 UNIT PER C.C. BE CHOSEN AS THE DIVIDING LEVEL

	Schick Positives with 0.03 or More Units of Antitoxin Per c.c.			Schick Negatives with Less Than 0.03 Units of Antitoxin per c.c.

Before Antigenic Stimulation	12	2.2	7.5	52	9.4	13.4
After Antigenic Stimulation	2	1.5	2.8	21	15.8	24.8

to a difference in the significance of the Schick reaction in naturally and artificially stimulated persons. The percentage of Schick positive persons having at least 0.03 unit of antitoxin is about half as great in those persons who have been artificially stimulated, as in those who have been naturally stimulated. On the other hand, the percentage of Schick negatives with less than 0.03 unit was approximately twice as great in a group after antigenic stimulation as in a group before antigenic stimulation. The difference in the distribution of the positives might be explained as due either to an allergic factor or to a dissimilarity in tissue permeability. The difference in the distribution of negatives might be explained as due to a lack of tissue susceptibility to diphtheria toxin, or as due to a local immunity resulting from increased permeability to antitoxin. These points are discussed later.

In Table IV are listed the results of

antigenic stimulation of those persons who were previously Schick positive although having 0.03 unit or more of antitoxin. The 3 persons remaining Schick positive were 3 of the 4 persons who showed a decrease in antitoxin concentration following antigenic stimulation. This perhaps indicates an error in the antitoxin titration either before or after stimulation. It would be a rather odd coincidence, however, that of the 4 such instances, 3 should have occurred in the persons who failed to become Schick negative. In each instance the positives were intense reactions ("14"). As has been stated, a number of sera were retitrated with a moderate difference in reading in only 1 of 16.

Most workers fail to find an antitoxin level below which all are positive. Experience with children has shown that most negatives have more than 0.03 unit, most positives less than 0.03 unit. Just what level will give the closest

approach to mutually exclusive groups has not yet been agreed upon. In our series the positive reactions both before and after antigenic stimulation are a better index of the underlying antitoxin concentrations than are the negatives. Persons remaining Schick positive after antigenic stimulation are more likely to have an antitoxin concentration below 0.03 unit than are Schick positive persons previous to antigenic stimulation. On the other hand, in those Schick positive persons who had been antigenically stimulated, a resulting Schick negative would appear to be a less reliable indication that the antitoxin concentration is more than 0.03 unit than it is in persons naturally Schick negative. It would seem from these figures that with antigenic stimulation we created a group of Schick negatives having a lower mean antitoxin level than has a naturally Schick negative group. This difference may be due to a tendency for antitoxin increase to lag behind the change from the Schick positive to Schick negative, or perhaps it may represent a fundamental difference in the response to artificial as contrasted with natural antigenic stimulation. The figures also indicate that a person who is Schick

positive in spite of a high antitoxin level may become Schick negative after artificial stimulation. Examination of the individual cases bears this out.

ANTITOXIN AND SEVERITY OF SCHICK REACTION

In Tables V and VI it may be noted that with increased intensity of the positive and combined reactions there is an increased probability that the person has less than 0.03 unit. In other words, if our figures are significant, the lower the antitoxin concentration the more severe the reaction.

The "23" combined reaction, as one might suspect, is the least reliable index of antitoxin concentration. Exactly 50 per cent of the 14 "23" reactions in Tables V and VI were associated with less than 0.03 unit. The "23" reading of the six possible combined readings is the one which might actually be a pseudo reaction. Likewise the "12" of the four possible positive readings is the one which might actually be a negative. It is of interest then, that these two Schick classifications show the greatest discrepancy with antitoxin concentration. This is true in spite of the fact that when by actual measurement a reaction was a "23" but the

difference in diameter was considered to be trifling, the reaction was called a "22" or a "33." The figures are too few of course to be conclusive, but we believe size could be used in gauging the underlying antitoxin.

RESPONSE TO ANTIGENIC STIMULATION

Tables VII and VIII and those following are devoted to the relationship and interrelationship of the Schick test, the antitoxin concentrations, and antigenic stimulation to age. Table VII is concerned with the increase in antitoxin level caused by the stimulus of a single Schick test dose in Schick negative persons. It may be noted that in general, the higher the antitoxin level before antigenic stimulation, the higher

the level reached after antigenic stimulation; that the absolute increase is greatest in those in whom the original antitoxin level is highest; and that as the original antitoxin concentration approaches the natural limit the ratio of the final to the original antitoxin concentration decreases.

As has been mentioned elsewhere, there is an error in the first and last groups which makes the series of ratios even more striking than indicated in the table. The choice of the figure 0.001 is deliberately a conservative one, since the concentration of cases below 0.002 points toward a mean figure far below 0.001. Perhaps many of this group have no antitoxin. Thus the ratio of 1:1,630 is probably too small. On the

TABLE VII
CORRELATION BETWEEN ANTITOXIN CONCENTRATION BEFORE AND AFTER ANTIGENIC
STIMULATION IN SCHICK NEGATIVE PERSONS

Antigen		Original Antitoxin Concentration

	Mean age	45	41	51	57	49	49	46	53	50

other hand, the pre-stimulation antitoxins were titrated only to 0.1 and consequently the ratio of 1:7 is probably too high.

The original antitoxin group which stands out as distinctly different from the rest in the series is the first one. While the ratio of final antitoxin to original antitoxin is very high as compared to the next highest ratio, it does fall naturally into the series of nine ratios. It is in the large absolute increase of antitoxin that the 0.001 group stands out as an exception. Whereas in the other members of the series the absolute increase of antitoxin is directly related to the original antitoxin level, the 0.001 group, instead of showing the smallest absolute increase, shows by far the greatest. Here then is a group of Schick negative persons who have trifling amounts of antitoxin or perhaps in most cases none, but are capable of responding to slight stimuli with a great increase in the antitoxin concentration. We have no evidence as to the meaning of this phenomenon. If observations by

others should confirm our findings, the way is opened to several problems of at least theoretic interest.

It would seem from Table VII and others that with increasing age the Schick reaction tends to become negative more rapidly than does the antitoxin concentration tend to reach the 0.03 level usually considered to indicate immunity.

Turning to Table VIII it may be seen that with Schick positive persons stimulated with a Schick test dose plus one, two or three doses of toxoid, the results are somewhat different, and also less significant, due to a scarcity of data. The antitoxic response, both absolute and relative, is slight as compared with the Schick negatives, in spite of the greater antigenic stimulation. Indeed, in our small series there was a group of 10 (boxed in Table VIII) in which the response was a negative one. The series is a small one, but only 1 of the 10 cases showed an increase in antitoxin concentration, and the cases were restricted to those receiving one or two

TABLE VIII

TABLE IX

ESTIMATED DIPHTHERIA CASE RATES PER 100,000 PERSONS WITH POSITIVE SCHICK TESTS*

Age Group	Case Rate per 100,000 Persons in Each Age Group	Case Rate per 100,000 Persons with Positive Schick Tests in Each Age Group	Per Cent Each Positive Schick Test Case Rate is of the 5-9 Rate
5-9	312	709	100
10-14	138	539	76
20-29	70	557	79
30-39	43	407	52
40-49	23	292	41
50-59	12	189	27
60	4	86	12

* These figures are based on over 20,000 cases in Michigan during 1924-1930, and on the percentage of Schick positive persons by age groups as compiled by Hope and Stallybrass in their *A Textbook of Public Health* from Park and Zingher's results. The 15-19 group is omitted because no results for ages 18 and 19 are given in Hope and Stallybrass's tabulation.

toxoid inoculations. The 1 case which increased became Schick negative after one inoculation. Of the remaining 6 receiving one inoculation, 5 remained positive and 1 became negative. With two inoculations all 3 remained positive. In the 0.001 group, in which there is a fairly large series, the advantage of repeated antigenic stimulation is not apparent as far as an increase of antitoxin is concerned. These same persons, however, showed a marked difference in the degree of shift from Schick positive to Schick negative, depending upon the number of toxoid inoculations, as may be noted below:

Antigenic Stimulation	Per cent of Schick Positive Originally Having 0.001 Unit Which Became Schick Negative After Antigenic Stimulation
Schick test dose plus one toxoid inoculation	25
Schick test dose plus two toxoid inoculations	58
Schick test dose plus three toxoid inoculations	80

The group with a very low antitoxin concentration before antigenic stimulation, whether positive or negative, was slightly younger than the other groups.

The figures of Park and Zingher show that the shift in Schick reaction from positive to negative in childhood and youth is continued through adult life. In Tables VII and VIII it would appear that the antitoxin concentrations also increase with age.

RELATIONSHIP OF AGE TO THE SIGNIFICANCE OF THE POSITIVE SCHICK TEST

In Table IX are shown estimated case rates per 100,000 positive Schick tests based on Michigan morbidity reports and upon Park and Zingher's data on the age distribution of Schick tests as compiled by Hope and Stallybrass.²⁵

We wish to point out that with increasing age the rate rapidly decreases. The application of New York data on the age distribution of positive Schick tests to Michigan case rates in order to obtain case rates among Schick posi-

tives by age groups does not seem to us objectionable since one would expect the rate of decline to be even greater, had we been able to use data from the more rural population of Michigan. Unless decreased exposure with age is the explanation for this phenomenon, a theory which seems improbable to us, this table suggests factors in the mechanism of diphtheria immunity which are as yet unexplained.

Further evidence that there are such factors, is suggested by the data in Table X. Here it appears that in spite of the general upward trend of antitoxin concentration with age, the percentage of persons with a negative Schick test and a low antitoxin concen-

tration is higher in the age group above 65 than in the group below. Conversely, the Schick positive state is more likely to be associated with a high antitoxin concentration in those under 40 than in those over 40. With increasing age perhaps one or more of the following phenomena take place in a few individuals:

1. Rate of antitoxin production increases.
2. Antitoxin already produced is more quickly mobilized and concentrated at a needed place.
3. Increasing specific or nonspecific permeability of tissue to antitoxin, or to the antitoxin vehicle if there be one, assures immunity at a lower blood antitoxin concentration.
4. Some other factor together with anti-

toxin makes antitoxin of relatively less importance in the protection of tissue, *e.g.*, decreased susceptibility to diphtheria toxin.

The coexistence of considerable antitoxin and a positive Schick test in early adult life might be explained as a corollary of the above; namely, that in some young adults due to an absolute or relative lack of the factors above, immunity is maintained only if the antitoxin concentration is at a high level. The trend of antitoxin concentration from youth to age, as may be noted in the last column of Table XIII does not, however, bear out such a theory unless possibly the effect of a large group of persons with decreasing antitoxin is cancelled by that of a large group with increasing antitoxin.

A simple explanation of the phenomenon would be that it is due to existence of an allergic response to the diphtheria toxin molecule; in other words, that what we have called a positive Schick in the high antitoxin persons was really a sensitivity reaction to the toxic principle of diphtheria toxin.

Table XI shows data after antigenic stimulation similar to that shown in Table X before stimulation. The data

are too few and irregular to justify any conclusions.

Table XII shows that in Schick positive adults, the greater the antigenic stimulus, the greater the immunologic response.

In Tables XIII and XIV are data showing the relationship of age to antitoxin concentration before and after antigenic stimulation. Table XIII shows more clearly what has been pointed out before, that with increasing age the percentage of persons with less than 0.03 unit decreases. In the first three decades tabulated, 41.7 per cent had less than 0.03 unit, while in the age period 50-79 only 30 per cent had less than 0.03 unit. How antitoxin response in Schick positive persons stimulated antigenically is related to age would be useful information, but as may be seen in Table XIV, our data are too few and irregular for any conclusion to be drawn.

Examination of Table XV shows a fairly definite increase in the percentage of Schick negatives with age, indeed a quite decidedly greater shift with age than was evidenced in the shift from below to above 0.03 unit of antitoxin.

TABLE XIII
RELATIONSHIP OF AGE TO ANTITOXIN CONCENTRATION PREVIOUS TO
ANTIGENIC STIMULATION

Age Group	Serum Antitoxin Levels				Total		Total Under 0.03 Units	
	0.001	0.002 To <0.03	0.03 To <0.175	0.175 or More	No.	%	No.	%
20-29	10	3	4	18	35	6.3	13	37.1
30-39	36	7	16	38	97	17.5	43	44.3
40-49	56	9	27	66	158	28.6	65	41.1
50-59	25	16	38	58	137	24.8	41	29.9
60-69	17	8	21	36	82	14.8	25	30.5
70-79	4	9	9	22	44	8.0	13	29.5
Total	148	52	115	238	553	100.0	200	36.1
% of Total	26.7	9.5	20.8	43.0	100.0
Mean Age	46	54	52	50	50	48

It will be noticed that the sensitivity reactions, the pseudos and combineds, occur in a younger age group than the negatives and positives. Interestingly enough, when the positives were given antigenic stimulation and again Schick tested a similar age relationship held true: the pseudos had a lower mean age than the negatives and the combineds than the positives. Apparently sensitization took place more readily in the

younger age group. Of the twelve combineds in Table XV, all of whom had been antigenically stimulated, 10 had been changed to negatives and 2 had been changed to pseudos.

Table XVI is included to complete the record. The data are too few to justify any conclusions.

We realize that as a practical measure of immunity to diphtheria the Schick test has proved its worth, and

therefore the level of circulating anti-toxin with which it is associated is not of great practical concern. But it is important immunologically. Our results, in accord with others, do not point to the existence of a level dividing all persons into the two exclusive groups of Schick positives and negatives, but our results do suggest a possible explanation for the several "Schick levels"

suggested in the literature. The anti-toxin concentration in the blood seems to lag behind the change from Schick positive to negative, and this lag seems to exist both in those developing a natural immunity and in those receiving artificial stimulation. One would conclude from this that Schick tests done at different intervals after either artificial or natural stimulation would

TABLE XVI
RELATIONSHIP OF AGE TO SCHICK REACTIONS FOLLOWING ANTIGENIC STIMULATION OF PERSONS PREVIOUSLY SCHICK POSITIVE

Age Group	Kind and Size of Schick Reaction										Total

be associated with different "Schick levels" of antitoxin. We feel this to be a point worthy of study.

SUMMARY

A study of the relationship between the Schick reaction, antitoxin concentration, antigenic stimulation, and age in male adults, was made in two Michigan hospitals for the insane. The following observations were made from the data:

1. Our results indicate that there is no antitoxin level in adults below which all Schick reactions are positive, and above which all are negative.

2. 0.03 unit seems a satisfactory level to use as a dividing point. At any rate we are not able to suggest a better level.

3. "False negatives" and "false positives," basing these terms on the assumption that 0.03 unit or more means immunity and less than 0.03 unit susceptibility, occur in different proportions, before and after antigenic stimulation.

4. While the percentage of Schick negatives and the concentration of antitoxin increases with age, the percentage of Schick negatives increases more rapidly with age than does the percentage of antitoxin concentrations at or above 0.03 unit.

5. Our data suggest that the intensity of reaction of the Schick test is correlated to a certain degree with the antitoxin concentration. That the relationship is not more marked suggests that the mere concentration of antitoxin in the blood stream is but one factor in the relationship of antitoxin to the Schick reaction.

6. We were unable to discover the significance of such tissue reactions as intensity of erythema, necrosis, vesiculation, marked pigmentation, "two zone reactions," etc.

7. It is suggested that in order to explain why the case rate among Schick positive per-

sons decreases with age, an immunity depending upon some factor other than circulating antitoxin must be postulated.

Official Reporting of Childhood Type of Tuberculosis

JESSAMINE S. WHITNEY, F.A.P.H.A.

Statistician, National Tuberculosis Association, New York, N. Y.

THE subject of the childhood type of tuberculosis has been receiving greater attention during the last two years, and tuberculin testing and X-raying of school children have become a more common procedure. To find out to what extent this change in emphasis has been reflected in official registration of the childhood type of tuberculosis cases, the National Tuberculosis Association recently instituted an inquiry. A brief questionnaire, very brief in fact, consisting of but two questions, was sent to every state health officer. These inquiries were: (1) Is the childhood type of tuberculosis reportable under the laws of your state? (2) How many cases of childhood type of tuberculosis were reported in your state in 1932?

The inquiries were made in 1933 and covered the calendar year 1932. It is quite evident from the replies that as yet there is no general effort to report childhood type of tuberculosis by physicians, and there is little attempt on the part of health officials to see that it is reported.

State laws require that tuberculosis, all forms, shall be officially reported, most of them requiring in addition that the organ or part affected shall be specified. The question at issue is whether the childhood type of tuberculosis comes within the meaning of these statutes. Is the childhood type of tuberculosis officially tuberculosis? The official attitude seems to be that of *laissez faire*, leaving to the individual physician the

interpretation of the statute. If such cases are reported they are included in the official register. Some physicians to be on the safe side report such cases; most do not.

All but one state officer, Utah, replied to the questionnaire. Of the 48 states—including the District of Columbia—replying, 29 said that there was no differentiation as to childhood type of tuberculosis, that *all* cases of tuberculosis were reportable. Fourteen states replied that the childhood type of tuberculosis was not reportable, which may mean that they have made their own interpretation of the statutes in this respect. The remaining 5 states replied that it was reportable, 2—Georgia and Michigan—having made it so by regulation.

It seems highly probable, however, from the general tenor of the replies that the states which replied simply "No" to the question of reporting childhood type tuberculosis meant to infer not that it was not reportable, but that the statutes or regulations did not specifically state that it should be reported; in other words, that no differentiation was made in regard to it.

If we incline to this interpretation, which seems a plausible one, then 43 of the 48 replies showed that there was no specific law or regulation to enforce the reporting of that type of tuberculosis.

From many of the replies it seems probable that "childhood type of tuberculosis" was confused with "tuberculosis in childhood," since in

answer to the second inquiry as to the number so reported some of the replies gave the number of reported cases of tuberculosis "under 15 years of age." Of course, these are two almost entirely separate categories. Children (under 15) may have every kind of tuberculosis, pulmonary, joint, bone, gland, miliary, meningeal, and intestinal. About 35 per cent of tuberculosis deaths among children are from meningeal tuberculosis.

But the term "childhood type of tuberculosis" is distinct from all the others specified above, and is the name which has been given to the pathological effect which the initial infection with tubercle bacilli has on the lung tissue and the tracheobronchial glands. Paradoxical as it may seem, "childhood type of tuberculosis" may occasionally occur in adults, and is often seen in adult Negroes and Indians, racial groups which have not been through generations exposed to tuberculous infection.

Only 9 states replied giving the actual number of cases of "childhood type tuberculosis." These totaled a little over 2,300. There were a few more numbers reported but as they were designated as "under 15" they have not been included. The states reporting actual figures for childhood type tuberculosis are those in which we know intensive special studies for tuberculosis among children are being conducted.

So much for what is being done. What should be the policy for the future? From the public health standpoint, should the childhood type tuberculosis be made specifically reportable? I think the answer for the time being must be "No." At the present time there is no unanimity of thinking as to the prognosis of such cases.

The outcome is dependent on the resistance of the tissues and the particular environmental conditions of the individual child. To some children it is a benign condition which takes care of

itself, ultimately heals, and confers a certain modicum of immunity; to other children it is the beginning of a morbid condition which needs very special care. So far as our limited figures tell the story to date, the numbers are about evenly divided between these two categories.

If we could be prescient and foresee which cases might develop into active cases of pulmonary tuberculosis, those might be made reportable, but to brand all such cases with the stamp of tuberculosis would be an injustice the effects of which might last through a generation.

Then there is the old but still potent reason which physicians always fall back on for not reporting tuberculosis cases; *viz.*, that nothing is done about it if they do report them. That is still true in many places. Then why add another category of reportable disease when facilities are meager, nonexistent, or non-operable for cases of disease already reported?

The public health policy back of all official reporting of disease, whether tuberculosis or any other communicable one, is to protect the public from further infection due to it. This protection is brought about by isolation of the case itself or by rigid aseptic technic in the home, and by examining all contacts, and immunizing them by a specific agent if known, or by giving them protective care.

How well is this carried out in the case of active pulmonary tuberculosis? Most special studies, except where very intensive contact work has been done, show that about 1 in 4 contacts is given a thorough physical examination. How can we expect the contacts of childhood type tuberculosis to receive any more thorough protective care? Of course, in childhood type tuberculosis the search in the immediate family for the active case or the carrier which has spread the infection is an impor-

tant public health measure. But the few statistical studies which have been made show that only about one-half of the cases of childhood type tuberculosis have any *known* family case to which the infection can be traced.

There is a third reason for not reporting childhood type tuberculosis. More and more the American Public Health Association *Appraisal Form* is coming into general use. Some of the ratios in it used to measure accomplishment in tuberculosis work are based on *active* cases of tuberculosis reported. For instance, 2 *new* cases reported each year to each annual death is 100 per cent attainment in reporting. The in-

clusion of all unearthed childhood type of tuberculosis cases in certain few areas where intensive school health examinations were carried on and the absence of such reports where no special work was carried on would make a lop-sided picture. If *every* case of childhood type tuberculosis in the United States could miraculously be discovered in a single year, we might then well advocate universal reporting of such cases. But as that millenium, as the word indicates, is a thousand years in the future, it seems better for the present to create no special laws for the compulsory reporting of childhood type tuberculosis.

AN OUTFIT FOR THE RAPID COLLECTION OF BLOOD SAMPLES

G. D. CUMMINGS, PH.D., AND F. C. FORSBECK, M.D.
Michigan Department of Health, Lansing, Mich.

THE necessity for collecting many blood samples during a clinic has called to our attention the inefficiency of using syringes. The outfit described in this note has greatly facilitated the collection of blood samples. It is simply a modification of the larger suction apparatus frequently used for obtaining blood for convalescent serum.

The parts of the outfit illustrated below are:

1. Shell vials, 16.5 x 58 mm. (5 c.c. capacity) with # 0 red rubber stoppers cut to length of $\frac{1}{4}$ ". (Black rubber stoppers and cork stoppers plug the needles.)

2. Two-way needles, 21 gauge, $1\frac{1}{2}$ " x $\frac{5}{8}$ ".

3. Suction assemblage: Rubber tubing, $\frac{3}{16}$ x $\frac{1}{16}$ " x 18" with cotton plugged mouthpiece, needle adapter, and 19 gauge, $\frac{3}{4}$ " needle.

Previous to the time of the clinic, the

rubber-stoppered vials and individually wrapped two-way needles have been sterilized. The vials are transported in aluminum boxes which measure 6"x12"x2" (162 vials). The needle point with the shorter shank is pushed through the rubber stopper so that the point projects just beyond the bottom of the stopper. The needle of the suction assemblage is then pushed through the stopper in like manner. With the mouthpiece in place, the free point of the two-way needle is inserted into a vein and suction is applied. After the vial has been filled, both needles are withdrawn and in a few moments a vial is ready for obtaining the next sample. Numbered adhesive labels have been found a great convenience. Such a label is readily transferable.

OUTFIT FOR COLLECTION OF BLOOD SAMPLES

The outfit has these advantages:

1. It is inexpensive, since all parts may be used repeatedly.
2. It is compact.
3. Sterilization at the clinic is unnecessary.
4. Blood may be drawn very quickly.
5. Clotted blood in syringes ceases to be a problem.
6. Blood is drawn directly into the final container.

7. The increased efficiency of the method results in a decreased confusion in the clinic and in a less concerned attitude on the part of the donor.

8. Serum may be readily separated from the clot by pouring.

9. The outfit may be conveniently used for whole blood samples and for blood culturing.

10. The particular size of vial found useful for our purpose fits the ordinary centrifuge shields and yields about 2.5 c.c. of serum.

State and Provincial Health Authorities Favor Pasteurized Milk

DR. CRUMBINE'S report indicated that 45 milk-borne epidemics had occurred during 1933 in 24 states, according to reports of state health officers, 44 of these epidemics having been traced to raw milk and one to raw cream.

Referring to undulant fever, Dr. Crumbine said:

The 4 epidemics of undulant fever reported for 1933, and none for 1932 would not seem to indicate a wide distribution of the disease or that it constituted an important health problem in relation to milk. But when we consider the 1,502 cases and 71 deaths re-

ported by the U. S. Public Health Service occurring during the fiscal year 1933, and the other large number of unreported and unrecognized cases that probably occurred, it must be admitted that undulant fever is a health and economic problem of major importance. Infected dairy herds are widely distributed over the United States and Canada, the rate of infection running from 5 to 50 per cent or higher.

If there were additional reasons needed for universal pasteurization of milk, the increasing menace of undulant fever would provide them.—

Health News, New York State Dept. of Health, 11, 26 (June 25), 1934.

A New Mechanism of Defence Against Bacteria Through the Use of Certain Foods*

LLOYD ARNOLD, M.D.

*Department of Bacteriology and Preventive Medicine, University of Illinois,
College of Medicine, Chicago, Ill.*

THE bacteriology of the intestinal tract has been investigated in this laboratory for the last few years and a new viewpoint has been developed (Arnold¹). Since this review article was published, several contributions have been made which extend our information relative to the adaptation of the bacterial flora within the lumen of the gastrointestinal tract, according to the physiological adaptation of the organism to its environment (Arnold and Kaufman,² Nedzel and Arnold,³ Johnson and Arnold,⁴ Nedzel, Stonecipher and Arnold,⁵ Seidmon and Arnold,⁶ Arnold, Korando and Ryan,⁷ and Arnold⁸).

In cooperation with Dr. Walter Eddy of the Teachers College of Columbia University, the use of certain foods has been investigated to determine if they will influence the defensive mechanism of the body against orally ingested bacteria. In order to maintain quantitative relationships we have restricted our experiments to the use of desiccated fruits and vegetables.

The technic outlined by Arnold, Korando and Ryan,⁷ who investigated the influence of cornstarch, sucrose, and banana powder on the acid-base

equilibrium and flora of the gastrointestinal tract of rats, has been carried out in these studies. This work showed that the use of these three carbohydrate foods did not alter the acid-base equilibrium or the intestinal flora of the gastrointestinal tract. There was, however, a change in the phage susceptibility of the *B. coli* flora. Table I gives the basal diets we have used in these experiments. We have

TABLE I

Basal Diet

Casein	18 per cent
Butter fat	3 per cent
Cod Liver Oil	2 per cent
Salt Mixture (Osborne & Mendel)	4 per cent
Carbohydrate	68 per cent

Fresh vegetables daily

1 gram dried yeast added daily
to feeding

Cornstarch — Control

Banana

* * * *

Apple

Tomato

Prune

carried out only one small experiment using five rats upon the prune diet. Only a few experiments have been carried out with the tomato diet and three experiments have been completed with the apple diet. The cornstarch and banana diets have been studied for 2 years. This paper will concern itself

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1931.

TABLE II

AVERAGE RATIOS OF GRAM-POSITIVE: GRAM-NEGATIVE BACTERIA IN GASTROINTESTINAL SEGMENTS

Diet	<i>Feces at Beginning of Diet</i>	<i>Stomach</i>	<i>Duo-denum</i>	<i>Jej.₁</i>	<i>Jej.₂</i>	<i>Jej.₃</i>	<i>Ileum</i>	<i>Caecum</i>	<i>Rectum</i>
Cornstarch	1:3	1:1	4:3	2:1	5:2	3:1	4:1	1:3	1:3
Apple	2:5	2:1	3:1	3:1	5:2	3:1	5:2	2:5	2:3
Banana	1:2	3:1	3:1	5:1	4:1	3:1	5:2	3:5	1:2

mainly with the comparison of cornstarch and banana diets. The information we have upon apple, tomato, and prune is only of a preliminary nature. Table II shows the Gram-positive and Gram-negative ratio of bacteria, determined by direct smears from various segments of the gastrointestinal tract of the rats fed cornstarch, apple, and banana for 3 weeks period of time. Table III shows the hydrogen-ion concentration of the various segments of the gastrointestinal tract, which was carried out on the same segments as reported in Table II. Both of these tables are averages of approximately 300 rats on cornstarch, 300 on banana, and 45 rats on apple diet. It will be seen that both the bacterial flora and the acid-base equilibrium within the lumen of the intestinal tract are approximately the same with the use of these three basal diets.

B. enteritides was fed by stomach tube to rats. The dose was 2.0 c.c. We have used various periods of feeding, but for this paper we will only report upon feeding experiments which were carried out as follows: Rats were placed on the basal diet for 1 week; *B. enteritides* was then administered by

stomach tube. The animals were weighed regularly and observed several times each day for diarrhea or other abnormal symptoms. A series of experiments was carried out in which two carbohydrates were used in the diet instead of the single addition as mentioned above. Thirty-four per cent banana powder and 34 per cent cornstarch were used; apple and cornstarch, and tomato and cornstarch were used in the same half and half proportions. Table IV gives the results of a series of such experiments in which diarrhea is recorded in the table. It will be noted that banana, apple, and prune diets protected the rats from diarrhea. Cornstarch and tomato diets did not seem to be protective. When banana was mixed with cornstarch in equal proportions this protective action seemed to have been lost. The tomato mixed with cornstarch did not differ from the tomato diet alone.

The average gain in weight of rats shown in Table IV has been recorded and is shown in Table V. It will be seen that the banana-fed rats have the greatest gain in weight. It does not seem that the growth factor is the one responsible for the resistance enjoyed

TABLE III

AVERAGE HYDROGEN-ION CONCENTRATION OF GASTROINTESTINAL SEGMENTS OF RATS ON VARIOUS DIETS

Diet	<i>Stomach</i>	<i>Duodenum</i>	<i>Jej.₁</i>	<i>Jej.₂</i>	<i>Jej.₃</i>	<i>Ileum</i>	<i>Caecum</i>	<i>Rectum</i>
Cornstarch	2.71	6.2	6.2	6.12	6.11	6.44	6.36	6.25
Apple	2.75	6.2	6.37	6.22	6.28	6.69	6.73	6.41
Banana	2.88	5.88	6.0	6.18	6.48	6.75	6.58	6.45

TABLE IV

DIARRHEA IN RATS ON VARIOUS DIETS AFTER *B. ENTERITIDES* FEEDING

Number Animals	Diet	Time of Occurrence of Diarrhea	Total Days
270	Cornstarch	4th to 10th day	6
270	Banana	No diarrhea	0
30	Apple	No diarrhea	0
30	Tomato	5th to 9th, 15th to 19th day	8
5	Prune	No diarrhea	0
15	Banana and Cornstarch	4th to 8th, 14th to 16th day	6
15	Apple and Cornstarch	4th day	1
15	Tomato and Cornstarch	4th to 8th, 14th to 16th day	6

by these animals against diarrhea after enteritides feeding.

Each cage contained 15 rats, in our experiments. Five rats were chosen and labeled, from each cage. Daily cultures of freshly obtained feces were carried out on these 5 rats from each cage. During the first 3 days after *B. enteritides* feeding, the feces were positive in most all instances. After this period of time, one or two colonies were sometimes observed, but there was no correlation between diarrhea and *B. enteritides* in the feces. The cornstarch series of rats showed positive *B. enteritides* longer than any other groups in this series.

Three weeks after the *B. enteritides* was administered, all the animals were sacrificed and organ cultures made from

spleen, kidney, liver, heart's blood and the gastrointestinal tract. Considerable variation was found in different cages, even on the same diet, in so far as organ cultures were concerned. Approximately one-third of the animals were found to have *B. enteritides* in the liver; one-fourth were found to have *B. enteritides* in the spleen. The kidney, heart's blood, and the ileum were negative for *B. enteritides*.

We have obtained 21 cultures of the *B. enteritides* group from various laboratories in this country and Europe. A strain sent us by Dr. Karl Meyer of the University of California has proved to be the most virulent strain we have tried in our experiments. This has been designated as the "KM" strain. This strain does not produce regular mortality in rats, even on the cornstarch diet. We have been unable to step up the virulency of this strain by animal passage. Morbidity, based upon the appearance of diarrhea, has been our test of virulency in this study.

B. enteritides isolated from various segments of the gastrointestinal tract and from the feces, as well as from the internal organs of rats fed the cornstarch and the banana diets, have been the same as the original strain, as judged from virulency, biochemical, colony formation, and antigenic tests.

A series of acute experiments were carried out in which rats were killed 1, 3, 6, 24 hours, and 1, 2, and 3 weeks

TABLE V

Diet	Average Weight at Beginning of Diet	Average Final Weight, 4 Weeks on Diet	Average Weight Gain per Rat
	Grams	Grams	Grams
Cornstarch	48	134	86
Banana	46	141	93
Apple	48	100	52
Tomato	60	115	55
Prune	78	114	36
Cornstarch and Banana	67	124	57
Cornstarch and Apple	65	117	52
Cornstarch and Tomato	73	118	45

after feeding *B. enteritides*. This was carried out with rats on cornstarch and banana diets. The distribution of *B. enteritides* within the lumen of the gastrointestinal tract, and in the liver and spleen, was approximately the same in both series.

Graduated doses of *B. enteritides* were injected intraperitoneally in rats to determine the smallest amount causing death in animals. The average dose was found to be 0.25 c.c. of a 24 hour old broth culture. Table VI shows the result of a series of experiments in which we used intraperitoneal injections of the above amount of *B. enteritides*. Three strains were used: the stock "KM" strain, a strain isolated from the feces of banana-fed rats, and a strain isolated from the feces of cornstarch-fed rats. These strains had the same biochemical reactions, colony formation, and antigenic properties. Table VI shows that the banana and cornstarch-fed rats have equal susceptibility to the "KM" strain when injected intraperitoneally. The strains of *B. enteritides* isolated from the feces of the banana-fed rats and cornstarch rats had the same virulency as determined by intraperitoneal injections. In feeding experiments the strains isolated from the banana-fed rats' organs and feces had the same diarrhea producing properties when fed to cornstarch rats as the original "KM" strain. The same was

true for *B. enteritides* isolated from feces of cornstarch-fed rats.

Three weeks after *B. enteritides* intra-gastric administration to rats on banana diet, intraperitoneal injection of the minimal lethal dose of the same antigen caused death on the 3rd and 4th day. The same experiment carried out with cornstarch-fed, enteritides-injected rats produced death on the 7th and 8th day. This would indicate some protection in the cornstarch-fed rats as a result of their experience with this antigen. These results are not conclusive but may indicate some protection.

Heat stable Salmonella toxins and ox-bile (Arnold¹) were given by mouth to the banana-fed rats in order to increase their susceptibility to *B. enteritides*. These gastrointestinal irritants did not seem to disturb the animals inasmuch as no diarrhea developed and the organ cultures were the same as the control series.

TABLE VII

FIFTY MICE ON EACH DIET FOR 1 WEEK, THEN
FED *B. ENTERITIDES* AND OBSERVED
FOR 4 WEEKS

Diet	Per Cent Mortality
General stock	96.0
Cornstarch	42.0
Banana	6.0

The first of the series of experiments upon mice will be included in this paper. Our stock diet for mice consists of equal amounts of "puppy meal" and cracked corn. This has been used for a number of years in this institution for our stock mouse colony. Table VII gives the results of the use of 150 mice, 50 for each of the three diets indicated. After 1 week on these respective diets, the animals were given *B. enteritides* by stomach tube and observed for 4 weeks. The mortality of those on the stock diet was 96 per cent, cornstarch diet 42 per cent, and the banana diet 6 per cent. These experiments are being continued. This table is included to indi-

TABLE VI

Diet	Strain <i>B. enteritides</i>	Result
Banana	"KM" stock	Died 48 hours
Banana	Banana feces strains	Died 7-10 days
Banana	Cornstarch feces strains	Died 7-10 days
Cornstarch	"KM" stock	Died 48 hours
Cornstarch	Banana feces strains	Died 7-10 days
Cornstarch	Cornstarch feces strains	Died 7-10 days

cate that mice may be better animals for assay of these factors than rats.

DISCUSSION

Standard basal diets, with variations in the carbohydrate components, were fed from the standpoint of calories, protein, inorganic salts, and vitamins. The diet promoted growth, produced good pelts, and the behavior of the animals was normal as far as we could determine. The differences in the results obtained, after the *B. enteritides* feeding, was first thought to be due to an interference with the self-disinfecting mechanism (Arnold¹). But, inasmuch as the intra-intestinal distribution was the same in both series of animals, this did not explain the absence of diarrhea in the banana-fed animals. We next thought of decreased permeability of the intestinal wall as a factor. But, inasmuch as the organ cultures were approximately the same in both series of animals, this mechanism again did not explain the differences in these experiments. When banana powder is used for the carbohydrate source of our basal diet instead of cornstarch, rats have the power of physiologically adapting themselves to *B. enteritides* administered by mouth. The intra-enteric and organ distribution of *B. enteritides* is the same in both banana- and cornstarch-fed series. No resistance is enjoyed by the banana-fed rats 3 to 6 weeks after *B. enteritides* injection, although one-third to one-fourth of these animals are liver and spleen carriers of *B. enteritides*. Wasserman and Citron¹⁰ explain the increased protection enjoyed after local vaccination as due to a re-tuning of the endothelial system and a consequent increase in physiological response by destroying invading bacteria *in situ*. Inasmuch as the bacteria in the organs are the same in both series, this explanation would not hold in our experiments.

Gulbrandsen⁹ discussed before the

Laboratory Section of this meeting, a change of bacteria from viable to non-viable forms within the stomach and duodenum. He showed that these same non-viable forms could be rendered viable again under certain conditions. In other words, the active acid-secreting stomach has more of a bacteriostatic than a bactericidal function. There is a complicated biological change going on within the lumen of the intestinal tract. Bacteria are rendered non-viable within the acid-secreting stomach and are revived and made viable in the lower segment of the small intestine and in the large intestine. In our experiments so far, when these non-viable forms penetrate the wall of the intestinal tract and are cultured from the internal organs, they show certain biochemical and antigenic alterations from the original strain. We are now investigating this aspect of the protective action of foods against pathogenic enteric bacteria, in laboratory animals.

Elements Involved in Determining the Qualifications of Health Officers*

E. L. BISHOP, M.D., F.A.P.H.A. (*Life Member*)
State Commissioner of Public Health, Nashville, Tenn.

IN considering the factors, a term I prefer to elements, with which we are faced in any attempt to determine even the basic qualifications of health officers, we must remember that public health work and preventive medicine draw upon the whole sum of human knowledge; that measures used in the conservation of life and health rest upon a knowledge of the arts and natural sciences as well as upon medical science. Moreover, we must have in mind personal qualifications as the complement to professional ability, and that, lacking either personal or professional fitness, an individual is unlikely to succeed in the execution of an effective public health program.

It requires no close study to bring out the endless complexities that present themselves for consideration when an attempt is made to formulate standards applicable to single groups or classes of health officials. Imagine how much more complex the question becomes when the elements of population units to be served and governmental jurisdictions are added. Can the same set of standards be required for the health officer of a city of 50,000 as for a city of 5,000,000? Will similar requirements be made for federal and state governments as for a rural county of 20,000 population?

One may well approach the whole question in fear and trembling, and one may be very sure that in the end he must compromise the ideal with the practical for, if he places his theoretical ideal so high as to be unattainable, he will have defeated not only the immediate but the ultimate objective. In this connection, I recall the experience last spring of our Committee on the Qualifications of Local Health Officers of the State and Territorial Health Officers' Conference. On that committee are men of the widest experience in public health training in both technical and administrative work, yet reference to the minutes shows the first action of the committee to have been limitation of consideration to systematic training in professional qualifications, thus immediately excluding consideration of all personal qualifications. While the next formal action was a resolution favoring the development of professional standards for health officers as a necessary step in safeguarding the public health, the committee as its third action still further limited the field for consideration by confining discussion to the qualifications of *local* health officers in charge of counties, districts, or other communities having a population of less than 50,000. Within these quite narrow limits, the committee then proceeded to formulate the following qualifications as its idea of the basis upon which, in its opinion, health officers should be chosen:

* Read at a Special Session on Professional Education of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

1. That the candidate hold a degree of Doctor of Medicine from a reputable medical school, and be eligible to take the examination for a license to practise medicine in the state. A license, however, was not considered necessary except where required by law in individual states.

It is considered highly desirable that any candidate for appointment shall have had at least 1 year of clinical experience, including 3 months in pediatrics and 3 months in infectious diseases, gained preferably in a hospital of acceptable standards.

2. That the candidate be not more than 35 years of age when first specializing in public health.

3. That where practicable the candidate be required to have had special training in the theory and practice of public health as follows:

A. He should have had not less than 1 year in residence at a recognized university school of public health.

B. In addition, he should have had not less than 6 weeks of field experience under proper supervision in a local health organization.

4. Pending the development of a reserve of personnel with qualifications specified in Item 3, appointing officers at their discretion may accept (a) carefully selected personnel who have had, or who will spend, from 3 to 6 months in a local health organization which is in position to supervise a course of field training, and (b) personnel who have taken in a university a graduate course of instruction in public health of not less than 3 months' duration, 6 weeks of which shall be spent in a well organized local health department which is in position to give supervision.

5. That all persons holding the position of health officer at the time these standards are adopted by a state be required to meet the requirements specified in Item 4-B.

I believed then and I believe now that this method of approach is sound, for it seems to me the only way in which we may solve this question that has so long vexed our minds is by determining its elements and considering each element in its relation to the whole. We may, I believe, dismiss the

question of personal qualifications by requiring the highest standard of character and the ability to work with, as well as for, the people to be served. Except in posts of larger administrative responsibility where ministerial duties still further complicate the picture, these simple requirements should suffice.

The development of professional standards of qualification is, however, not quite so easy of solution. Here we must consider not only the varying size of population units to be served and other factors to which reference has been made, but also the varying per capita wealth that governs the capacity to provide public health service. I do not mean that the compromise of the theoretical ideal with the practical should be destructive of high standards but on the contrary that it should be a constantly moving standard, always approaching the ideal but never stifling growth and development of sound public health organization.

In this brief introduction to the problem concerned with factors involved in determining the qualifications of health officers, I have not attempted to point out nor to catalogue separately all of the many factors we shall have to consider. I have, however, tried to emphasize the need for a sane and practical approach in dealing with the question of securing more effective service through sound standards of qualification. That satisfactory results may be attained is supported by the experience of the Province of Quebec where almost all full-time health officers—even health officers serving the smaller rural jurisdictions—have had “not less than 1 year in residence at a recognized school of public health.”

An Epidemiological and Clinical Study of an Influenza Epidemic in a College Community*

CHARLES E. SHEPARD, M.D.

Stanford University, Stanford University, Calif.

SINCE the pandemic of influenza in 1918-1920, sporadic cases have appeared constantly, epidemics have appeared focally and generally with almost cyclic regularity. Dublin reports in a study of mortality rates that a regular increase in deaths reported from influenza has occurred at approximately 3 year intervals since the war. An increase in influenza morbidity and mortality had been predicted for the year 1932-1933.

Influenza appeared in epidemic proportions during the fall of 1932 among college students at Stanford University. Although the attack rate was relatively low (7.2 per cent), the course of the disease fairly mild, and complications without serious consequence, there were certain interesting features of the epidemic which justify careful study and report. This was one of the first communities in continental United States to report on the appearance of influenza in epidemic proportions in the fall of 1932. It is frequently difficult to secure accurate records on influenza outbreaks in given population groups because of lack in uniformity of diagnoses and report on cases. It is much easier to se-

cure accurate reports on epidemic outbreaks in a college group. Central health supervision, uniform records and close contact with students make possible more comprehensive reports on epidemics. When students at Stanford University become ill they report either to their own physicians, directly to the hospital located on the campus, or to staff physicians in the offices of the Student Health Services. Students who are not seen in the Health Services at the onset of acute illnesses usually report there after recovery for the purpose of petitioning for leaves of absence for the period during which they were unable to attend classes. It is, therefore, possible to make contact with most students who have been absent because of illness, to establish with some precision the diagnosis of the disease and its complications, and to determine disability periods. The majority of students who became ill during this epidemic reported early to the Health Service where careful histories were recorded and where positive diagnoses of influenza were based on certain definite criteria acceptable to all staff physicians. A number of cases have been omitted from this report which ran mild or atypical courses. The report does not therefore represent the total number of probable cases, but only the total number of cases in which diagnoses could be satisfactorily established.

* From the Men Students' Health Service in the School of Hygiene and Physical Education in Collaboration with Dr. Walter H. Brown of the University Health Service and Miss Yvonne Fay, Public Health Nurse.

EPIDEMIOLOGY

Several scattered cases were reported during October. Early in November there was a sudden increase in cases reported by date of onset so that between November 6 and November 14 the incidence had reached the peak. From that date there was a rapid decline to November 19 and a second rise in incidence to a similar peak on November 21. Following this date there occurred a rapid subsidence of the epidemic. Chart I represents the incidence by date of onset beginning with the first case reported on October 6 and extending to December 6 when the study was terminated. The occurrence of the second high point in incidence cannot be explained except that on November 19 there was a general migration of students from the campus to Berkeley because of a football game. The second peak in incidence occurred 2 days after this game. The rapid increase in incidence and the more rapid decline is interesting. No special control measures were instituted except for early segregation of cases. Had such measures been attempted the incline might have been less rapid, the decline might have

been more gradual and administrative management would have been easier.

It has been difficult to determine with any accuracy either the spread through contacts or the incubation periods because of the close association between students in classrooms, dormitories, gymnasias, common eating halls, and in university gatherings. A study was made of contacts in several of the men's dormitories, but very little information was gained. It is nevertheless surprising to learn that room-mates of students who became ill rarely contracted the disease. In a study of incidence in a series of 89 cases who had room-mates, it was found that only 9 occupants of the same room became ill. In 7 of this number the room-mate came down with the disease between 48 and 72 hours after the other occupant of the room had become ill. This occurred in each case in spite of the fact that the first victim had been early removed from the room. This combined with the fact that the incidence rate showed definite increases within 48 to 72 hours after general university gatherings suggests that the incubation period is fairly short.

 INFLUENZA EPIDEMIC—AUTUMN 1932
 SPECIFIC MORBIDITY RATES IN THE VARIOUS LIVING GROUPS

	En-cina	Bran-ner	Toyon	Se-quoia	Union	Roble	Fra-ternities	Sorori-ties	Cam-pus	Palo Alto	Other
Popula-tion	507	143	170	146	110	203	652	236	81	307	133
No. of cases	57	9	18	7	6	19	49	15	3	15	3
Attack Rates	11.2%	6.2%	10.5%	4.7%	5.4%	9.3%	7.5%	6.3%	3.7%	4.8%	2.2%

A study of incidence by age is limited because there is little variation in the age group studied. No figures are available to show the average age of all students in college, but statistics compiled by the university giving the average age of college matriculants entering during the first year, first and second year, third and fourth year, and in graduate standing give some light on the subject. The largest number of cases occurred between ages 20 and 21, but the disease was more frequent in students under 20 than over 21. Although the age spread is too small to be of particular moment, still it is significant that students of average graduate age were relatively free from attack. Many upper class and graduate students were on the campus during the epidemic of 1929. This leads one to suspect that the younger age groups may have been more susceptible. It is interesting to note that the first reported case was in a graduate student aged 22 and that no cases were reported in students over 25 years of age while the average age of graduate matriculants is 29 years and graduate students make up roughly one-third of the student population. In general, the earliest cases reported were first year students while

the disease later spread to upper age groups.

The 200 cases here reported include 41 women students. Since there are only 500 women students in the university, no comparison in attack rates by age is possible, but if it may be assumed that the total group includes similar numbers of reported cases and substantiated diagnoses in men and women students, the incidence was slightly higher in women students than in men students. The attack rate was 9 per cent for women as compared with 7 per cent for men. The incidence was somewhat higher in the lower age groups in women than in men, 46 per cent of cases in women being in the first year class. The highest incidence in women occurred between 18 and 19, as compared with 20 and 21 for the men.

Studies on the geographical distribution of the influenza cases revealed certain interesting facts. Most of the students attending the university live on the campus, either in dormitories or fraternities or in private rooms. A smaller number live in town or commute from nearby points. The relative morbidity rates in these various living groups is shown in Table I. This shows the number of students making

up each group, the number of influenza cases which occurred in each group and the attack rates by groups. It was found that higher morbidity rates occurred in the two dormitories occupied chiefly by first year students. There is no explanation for the high morbidity rate in Toyon Hall which is occupied by Sophomores, Juniors and Seniors, but most of the victims in this hall were sophomores whose average age was found to be slightly less than 20 years. No relation between general sanitary conditions of the living groups and morbidity rate could be determined. The relatively low attack rates in off-campus groups does not give quite a true picture of the situation since many of these students became ill after the campus epidemic had subsided and after the study had been terminated. The attack rate in this epidemic has been unusually low—the highest in any one living group being 11.2 per cent, the lowest, 2.2 per cent. The attack rate has been much higher in reports from other communities during this epidemic.

DISABILITY RATES

A relatively short period of disability characterized the epidemic. Disability is here defined as the number of days a student was forced by virtue of his illness to absent himself from his class-work. It does not include the rather long period of convalescence during which time the student was able to carry on at least part of his work. Nor does it include disability caused by complications. The epidemic produced a total of 882 student disability days during the 66 days included in the study. This means that an average of 13 students were disabled on each day of the study. The average period of disability was from 3 to 5 days and 91 per cent of the group were disabled from 2 to 6 days. The 3 cases which were disabled 11 and 12 days were patients who had recovered

from the first attack but who had relapses (without complications) before they were able to return to work. The total disability time was considerably prolonged through the superimposition of complications. Several students were forced to leave school for the remainder of the quarter because of complications, failure to recover from weakness, or because of delinquency in class work. Many were partially disabled through persistent complications, many suffered from common colds following influenza. While the actual disability time of influenza has been short, the total and partial disability resulting from complications and sequelae have brought heavy economic and health liabilities to its victims.

DIAGNOSIS

The clinical picture of influenza has been clearly described by various authors and the diagnosis should not be particularly difficult in the known presence of an epidemic unless the attack and course are unusually mild or unless the symptom complex is early confused with superimposed complications. It is nevertheless surprising how frequently the diagnosis is made on what would appear to be insufficient clinical evidence. There is a tendency on the part of physicians to over-diagnose the disease. Many cases of influenza would probably be diagnosed as common colds in the absence of an epidemic. The increase in number of acute upper respiratory infections which occurs coincidentally with influenza tends further to confuse the diagnosis and to decrease the accuracy of reports. A careful study of onset symptoms in order of their appearance, frequency of occurrence and severity and strict observance of the time of appearance and relative severity of localizing symptoms would reduce confusion in diagnosis and determine more accurately the chronology of complications. The

diagnosis of influenza should not be safely made in the absence of constitutional symptoms or when symptoms referable to the upper respiratory tract predominate from the onset.

An unusual opportunity has been presented in this study to reduce confusion in diagnosis, to establish with more than usual accuracy and with considerable uniformity the onset symptoms in order of frequency and severity and to observe clearly the appearance of complicating symptoms. Every effort has been made in studying this group to establish accurate diagnoses and our efforts have been facilitated by several factors which cannot always be secured in an epidemic study in less well controlled groups of the population. Most of the cases reported early so that accurate history of onset was made possible. The accuracy of histories was increased by the fact that patients were intelligent and coöperative, and because physicians were uniform in their methods of approach. Most of the cases were under observation in the same hospital where progress was followed daily by a public health nurse. Cases were

also watched uniformly through the period of convalescence. Positive diagnosis has been based upon the presence of a general constitutional reaction coming on suddenly or within 12 to 24 hours of the first complaint of not feeling well. This reaction usually included fever, prostration, headache, malaise, backache, and chilly sensations. It was commonly accompanied by localizing symptoms such as dry cough, sore throat, dry or obstructed nose, soreness of the eyes, nausea, and occasionally by vomiting and diarrhea. The finding of normal or lower than normal white blood counts with lowered polymorphonuclear elements or relative lymphocytosis further confirmed the diagnosis. The finding of leukopenia was found to be reduced in value because it is early changed by the superimposition of complications.

Occasionally the prostration was mild, fever was moderate, and there was little headache or general malaise; yet there were also no predominant upper respiratory symptoms, so that in the presence of an epidemic one would be forced to consider the diagnosis as

TABLE II

ONSET SYMPTOMS IN ORDER OF FREQUENCY AND SEVERITY, INFLUENZA EPIDEMIC, STANFORD UNIVERSITY, AUTUMN, 1932

Symptom *	—	+	++	+++	++++	+++++
Fever *	3	19	66	47	43	22

103.1-104 = +++++

influenza. These cases were few. More frequently confusion in diagnosis resulted from early appearance of upper respiratory symptoms superimposed upon mild constitutional reactions which might or might not have justified a primary diagnosis of influenza. Unless careful history revealed the definite constitutional reactions of influenza, such cases were diagnosed as upper respiratory disease. It is probable that certain cases of mild influenza with early upper respiratory complications have not therefore been included in the series studied. The study has been limited to 200 cases in which the data secured led to unchallenged diagnosis. Since the epidemic began soon after the opening of college and had practically subsided by December 1, only those cases occurring between October 6 and December 6 are included in the report.

Some cases when first seen were already complaining chiefly of sinusitis, bronchitis, or another upper respiratory condition; but most cases were seen early when the general constitutional reactions were at or near the peak. A careful study was made in the 200 cases forming this series to determine the onset symptoms with reference both to predominant complaint and relative severity. In order to secure more uniformity in reporting complaints in accordance with their importance both as seen by the patient and as observed by the physician we have made use of a simple code which is familiar to all examining physicians in the Health Service and which is used extensively in evaluating findings. Although such a code is valuable only to those who use it uniformly it gives simply and concisely a quantitative estimation of the severity and relative importance of symptoms.

Table II shows the chief symptoms at onset with frequency of occurrence in 200 cases and the relative severity as observed by the patient and by the

examiner. Quantitative estimation of severity is outlined in the key.

It will be observed that fever was the most common and tended to be the most acute symptom. It was present at onset in all but 3 cases. The onset temperature was most commonly between 100.1° and 101° F. but was more often higher than lower, in 90 cases being between 101.1° and 103° . Prostration was present in all but 8 cases. It was more often severe than mild, and in 4 cases was measured in almost complete collapse. The extent of prostration was not definitely related to the degree of fever, often those with moderate fever were very much prostrated. Headache was the next most common complaint. It was present in 170 cases and was more often slight or moderate than severe. It was usually frontal, but occasionally was coronal and more rarely (frequently associated with nausea) it was occipital. General muscle-joint aching or malaise was present in all but 57 cases. It was also described more frequently as mild than severe, usually moderate. Cough was present at the onset in about half the cases. It became more frequently a complaint as the epidemic advanced. It was almost always dry, hacking and irritative without expectoration. It was often associated with a feeling of tightness in the upper chest and the act of coughing was rather painful. Examination of the chest at this time revealed either no auscultatory changes or only harsh breath sounds heard over the roots or lung bases. Evidence of bronchial exudate was rare at this time. A symptom which occurred less severely and which was complained of less frequently was backache. It was offered as a complaint by 79 patients. "Sore throat" was one of the onset complaints of 78 patients. It was not an outstanding onset symptom, and examination revealed nothing beyond a generalized injection of the mucous membranes

of the fauces which usually extended down the posterior pharyngeal wall. No exudate was present. Forty-five patients complained of chills, or chilly sensations at the onset. Careful questioning failed to reveal that these were characteristic chills, but rather that the extremities felt cold and that the patient felt generally "chilly."

Only 29 patients complained of nasal symptoms. The usual complaint was that the nose felt dry and irritated or obstructed. Excess secretion was not present at this time. A number of patients complained of soreness of the eyes. Others who did not offer this as a complaint were observed to shield their eyes from the light. Slight injections of the conjunctivae were common findings in these cases. Gastrointestinal symptoms were fairly common. The usual onset symptoms in several cases were preceded 12 to 24 hours by an acute enteritis with nausea, vomiting and diarrhea, usually without cramps and without fever. The condition presented a picture of so-called acute food poisoning. About the time this condition began to improve, acute prostration, fever, malaise, etc., supervened. In other cases the intestinal symptoms coincided with onset of fever, prostration, etc. Nausea was the most frequent gastrointestinal symptom, but this is frequently associated with sudden high fever and so is found out of order in the list of gastrointestinal symptoms. In this connection it is interesting to note that the California Public Health Reports showed an increase in cases of food poisoning coincidental with the increase in cases of influenza at that time.

A review of onset symptoms reveals the fact that onset is usually associated with a general constitutional reaction—fever, prostration, headache and malaise, in that order of frequency and severity; that the most common localizing symptom was cough, which was

more frequently a complaint during the later period of the epidemic, and was always an early complaint in those who later developed bronchitis or pneumonia; that at onset it was dry, hacking and often painful. Sore throat, though a common localizing onset symptom was found on examination to be due to a general pharyngeal injection. Gastrointestinal symptoms were rather common onset or even precursory symptoms which deserve more thorough study since they often tend to confuse the early picture.

COMPLICATIONS

In 81 cases included in this study the acute constitutional reaction and localizing symptoms were not followed by findings leading to the diagnosis of complicating disease. Although this number is relatively small the fact that uncomplicated cases occur should lessen the confusion in diagnosis and make easier the description of influenza as a clinical syndrome. In these cases the course was rapid, duration was short, and the convalescent period was brief, so that one is led to believe that influenza is not a serious disease *per se*, but that morbidity and mortality are increased because of complications.

The most common complications in this epidemic have been acute bronchitis and acute sinusitis or a combination of the two. Such diagnoses were made following influenzal onset in 43 cases. Such cases have been largely responsible for the prolonged disability period and slow convalescence. Acute tonsillitis occurred as a complication in 6 cases, and acute otitis media appeared in 5 cases. One case of acute cystitis and one case of focal arthritis occurred either coincidentally or as complications. In 2 cases the onset symptoms were shortly followed by the appearance of dry pleurisy, one of which developed pneumonia. Broncho-pneumonia is a common complication in epidemic in-

fluenza. It occurred in 11 cases in this series, was fairly mild in all but 3 patients who became critically ill. It was a more common complication of the later period of the epidemic, as was acute bronchitis, and the 3 critical cases of pneumonia, all became ill from influenza during the last week of the epidemic study.

SEQUELAE

Relapse occurred in 2 cases with a primary disability period and in 2 after return to classes. A large number of patients after recovery from influenza suffered from common colds. Among other sequelae must be mentioned the marked lowering in the threshold to fatigue, residual tachycardia, night sweats, anorexia and general muscular weakness. Three students were forced to discontinue their school work because of marked weakness of extra-ocular muscles. Six were unable to finish the school quarter because of the persistence of marked general weakness.

SUMMARY

The appearance of influenza among college students at Stanford University in the fall of 1932 presented an opportunity for studying intimately the disease in its epidemic form. Conditions were unusually favorable for such a study since the health supervision in the college community is centrally controlled, most of the cases have reported early, have remained under observation during the course of the disease and during convalescence, and incidence, geographic distribution, and disability were easily determined. It was possible to establish diagnoses with greater accuracy than is often obtained in an epidemic study, since certain definite symptomatic criteria have been set up for the purpose and observed uniformly by members of the medical staff. Because of careful histories and the re-

porting of symptoms by time of appearance, frequency and severity, it was possible to contribute further to those criteria upon which the diagnosis of influenza should be founded. Finally, it was possible by the same methods to identify the complications in order of frequency and importance. Although a slightly larger number of cases was reported, 200 cases were selected for the study, the selection being based on accurate reports, unchallenged diagnoses, and complete follow-up study. The epidemic reached its peak very rapidly, then after a short period in which the number of reported cases diminished there appeared a second peak. This was followed by a rapid and final decline. The height of the epidemic occurred between November 6 and 27. Very few new cases were reported after that time. The importance of spread through contact could not be determined with accuracy, but there were surprisingly few instances where room-mates of victims were affected, and there appeared to be some relation between university gatherings and increase in reported cases. From the latter observation and the study of the occasional room-mates who were affected, it appears that the incubation period is short, probably usually 48-72 hours.

The attack rates were definitely higher in the lower age groups. The incidence was highest in occupants of first year dormitories and in sophomores living in other dormitories. The incidence in students of average age of graduate standing was surprisingly low. The incidence was slightly higher and the disability period was slightly longer in women students than in men students. The total disability caused by the disease was rather low and the average disability period per student was relatively short—in 91 per cent of the group the period of disability was between 3 and 5 days. Confusion in

diagnosis occurred chiefly in the occasional mild cases and when complications occurred early in the course of the disease. A careful study of symptoms at onset in regard to time of appearance, frequency of occurrence and relative severity has assisted greatly in

reducing this confusion. Complications were very common and the total and partial disability resulting from complications and sequellae was high, producing much greater economic loss and impaired health than was caused by influenza *per se*.

Maternity Benefits from Public Sources—Sweden

MATERNITY aid from public sources was first introduced by way of experiment in four provinces of Sweden during 1931, but within the next two years it was gradually extended to the entire country. This aid is given to women members of social-insurance funds and to noninsured women. In the case of insured women the insurance funds are required to pay maternity benefits, for which they are later reimbursed by the national treasury. Formerly the payment of maternity benefits was optional. The benefits amount now to 2 kronas daily, instead of 1 krona (par value about 27 cents) as formerly, and are paid for a period of 30 to 56 days, instead of 14 to 42 days. In addition free attendance by a midwife or hospital care is now provided.

The new regulations governing the sickness insurance funds also permit a nonemployed woman to become a member for sickness insurance only. At the time of childbirth such a woman is entitled to free attendance by a midwife and to maternity benefit of 2 kronas daily for at least 30 days. Since the premiums for this kind of insurance amount to less than a half krona a

month, a woman of even small means may obtain the above benefits.

The most significant feature of this new system of maternity aid is, according to the students of social welfare in Sweden, the provision of maternity aid to noninsured women, whose income is below a certain amount. It has been calculated that out of the 93,000 annual cases of childbirth in Sweden 70,000 belong in this category. The aid is 1 krona a day paid for a minimum of 30 days, and for 56 days in the cases of women employed in industries protected by the labor code. No free attendance by a midwife is provided to noninsured women.

Application for maternity benefits must be made at least 60 days before the expected birth of the child. The purpose of this requirement is to enable the disbursing organization to give the woman prenatal advice and, if necessary, make arrangements for her care during pregnancy and confinement and for the care of the child. Plans are being made for coöperation with child health centers and similar organizations.—*Tidskrift för Barnavord och Ungdomsskydd*, Stockholm, No. 1, 1934.

Standard Blood Agar Plate in the Control of Scarlet Fever*

Experience of a Rural Health Unit

H. R. O'BRIEN, M.D., F.A.P.H.A. AND R. P. FOWLER

Lorain County, District Department of Health, Oberlin, Ohio

IN 1929 blood agar plates were introduced by Dr. C. D. Barrett in the work of the Lorain County Health Department in the control of scarlet fever. This study reviews our experience with these plates from January 1, 1931, through August, 1933. In this time we had 339 cases of scarlet fever, 751 suspects, and 16 cases diagnosed as septic sore throat. How we used blood agar plates and our conclusions as to their usefulness is told in this paper.

Ours is a district health department in northern Ohio serving a county of 40,000 people scattered over 10 villages and 20 townships in an area of 476 square miles. It is a department of moderate size, with a full-time health officer, 3 nurses, a sanitary officer, a laboratory man, and a clerk. The laboratory man is also the milk inspector. Our laboratory is a small room, 9' x 14', but we make the ordinary bacteriological determinations, except for Wassermanns.

When a case of scarlet fever is first seen, a throat culture is taken routinely, from both tonsillar regions if possible. In the laboratory sterile normal saline is poured into the tube, covering the swab. The tube is shaken and set aside. To a tube of ordinary melted

agar cooled to 40°-42°C. a loop of the saline suspension is added, then 0.5 c.c. of beef blood (preserved with citrate in the refrigerator). The whole is rolled, then poured into a plate, and incubated. After approximately 18 and 42 hours the plate is examined for the characteristic colonies of the hemolytic streptococcus, beta type. Release culture were taken 18 days after the onset. If positive, still other cultures were taken until negative.

We have had no epidemics of scarlet fever, but have shared the general increase which most of Ohio has experienced. The table deals with 103 cases in 1931, 151 in 1932, and 85 in the first 9 months of 1933. This is an annual morbidity rate of 306 per 100,000. Cases have been quarantined on the diagnosis of practising physicians or of the health commissioner.

TABLE I

Early culture (when first seen) positive	165
First culture negative, a later culture positive	38
First culture negative, later cultures negative	53
First culture negative, no release culture shown	15
No early culture taken, later culture positive	17
No early culture taken, later culture negative	27
No cultures recorded at all	24
Total cases cultured	315

*Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 17, 1933.

Of the 339 positive cases of scarlet fever dealt with, Table I summarizes the results of cultures:

Of the 271 cases with a culture within a week of onset, 165, or 60.9 per cent, gave a positive culture. Of the 106 negative at first, 38 were later positive. Special effort to reculture early negatives was seldom possible, or more positives would probably have been obtained. Of the 44 who had no early culture, 17 were later positive. Thus of the 315, 220, or 70.2 per cent, were positive at some time.

We made some study of the symptoms accompanying scarlet fever. In 188 cases in which report was made, peeling occurred in 161, or 83.0 per cent. Of the cases whose cultures were always negative, 34 peeled, 9 did not. Of those who peeled 104 (66.7 per cent) had positive cultures at some time, 52 were negative, and 6 had no cultures recorded. In 168 cases there is a definite statement on the question of vomiting. This occurred in 111 cases, or 66.1 per cent.

Most of our cases of scarlet fever were quarantined without reference to the culture, but frequently in doubtful cases we waited for a positive culture and considered it so much additional evidence. It aided when the rash was very faint, or hard to distinguish from other rashes.

The culture was uniformly employed when the question of release arose. Ohio now quarantines at least 21 days for scarlet fever. At 18 days after the onset we took a throat culture. If negative, the patient was discharged at 21 days. If positive, the culture was repeated until negative. Usually the throat cleared up rapidly. A continued positive culture was almost invariably associated with enlarged tonsils or enlarged cervical glands. An otitis media would give a positive culture as long as the discharge continued, long after the throat was negative. One high school

boy developed a maxillary sinusitis following scarlet fever and a supra-orbital abscess. Cultures from the throat became negative, but those from the nose and the incised abscess cavity continued positive until the supraorbital wound healed.

We used the cultures quite widely in examining suspects. If scarlet fever appeared in a class in school, the other pupils in the room were examined. Those with sore throats or those arousing suspicion in other ways were cultured. Sometimes a positive culture, added to a suspicious tongue or an almost faded rash, made a diagnosis possible and the child was quarantined. In other cases while the evidence was not conclusive enough to call it definitely scarlet fever, the child was excluded from school as a probable carrier until his throat became clear. We made no study of the virulence of organisms found in the throats of such carriers.

In all cultures were made in 751 suspected cases, aside from those quarantined. Of these 181, or 24.1 per cent were positive. Some of those negative might have proved positive on reculturing, but by imposing some degree of restraint on those found positive, we lessened considerably the number of scarlet fever organisms in circulation. It is noteworthy that of the suspects 40 showed some degree of peeling. Of those peeling 15, or 37.5 per cent, had positive throat cultures. Quite possibly we should have quarantined them. By way of comparison, 46.3 per cent of the quarantined cases who peeled had one or more positive release cultures.

Cultures in suspicious cases encountered late in the disease were especially valuable in differential diagnosis. A child with a running ear and a history of a cold and a rash some weeks previously might have had measles or scarlet fever. If the culture showed hemolytic streptococci of the

beta type, we were inclined to consider it scarlet and isolate.

A boy with an infected finger developed an axillary abscess. Later a general punctate eruption appeared. The abscess yielded *Streptococcus hemolyticus*, beta type. The throat was never sore. Here we had scarlet fever resulting from an invasion of the body by way of the finger instead of the usual avenue, the throat.

In 1930 a farmer had a blistered finger, which developed a severe infection of the finger. Culture of the incision showed *Streptococcus hemolyticus* beta. In 3 days scarlet fever appeared in 1 child, who died. Two other children also had scarlet fever.

A baby developed influenza, then empyema, and later a general punctate eruption. The throat never showed hemolytic streptococci, the pleural cavity did so consistently until it healed. The child peeled.

A boy treated in a hospital for extensive burns on the leg developed scarlet fever. He was taken home, where he recovered from his scarlet fever. His throat culture was negative and he was released. Three weeks later another child in the household developed scarlet fever. The burned boy's throat was again positive, possibly from the reservoir in the leg. After his throat became negative, he was held until his leg was healed. No further scarlet fever appeared.

Cultures were of value in still another throat condition. Severe sore throat is found fairly often, without rash or strawberry tongue, with positive beta type cultures. Almost by definition these are septic sore throat. Sometimes they are clinically mistaken for diphtheria. In such cases we run both a Loeffler slant and a blood agar plate. We would point out that both can be positive in an individual; in one of our cases it took a virulence test to show that it was not diphtheria, but septic sore throat. To a health department doing general milk work it is of special value to know whether a sore throat in the family of a milk dealer is of the septic-sore-throat-scarlet-fever family or not.

CONCLUSION

It is in locating the suspicious or sub-clinical case of scarlet fever, or in differentiating it from confusing diseases that we have found these blood agar plates most valuable. We do not consider them absolute.

Much remains to be understood about this organism, its exact relationship to scarlet fever, its occurrence in the ordinary population, etc. But by considering the results of these cultures as part of the total evidence in each case, we are sure that we have been greatly helped. We would recommend the procedure to other small health departments.

Medical Supervision in the Public Schools*

WILLIAM L. GOULD, M.D.

Medical Supervisor of Schools, Albany, N. Y.

WHAT are the functions of the School Medical Staff? From the medical point of view the answer may be given in one word—prevention. A general campaign is carried on to prevent the spread of contagious and communicable diseases. The pupils are examined in an attempt to prevent possible defects from becoming manifest and actual defects from getting worse. The aid of the parent and the private physician is sought for both preventive and remedial measures. Handicapped children are given special consideration. Employees and pupil candidates for working papers and athletic contests are examined. No actual therapy is carried on in the schools. There is so much in the program of preventive medicine that at no time should it be necessary for a school physician or nurse to partake of any actual therapeutic procedures except, of course, to render first aid in emergencies.

From the school viewpoint the functions of its medical staff may be summed up in one word—education. The pupils are taught the value of the periodic health examination and the importance of the correction of any defects found. Care of the eyes, ears, teeth, heart, lungs, nervous and skeletal systems are stressed. The importance of proper sanitation, hygiene, fresh air, sunshine, cleanliness, proper food, ex-

ercise, rest and good posture are emphasized. Supposed mysticisms of medicine are exposed, making the pupil more health conscious. He becomes receptive to proper medical care and attention. Just as bad health hampers education, good health aids it. Boards of education have realized the value of this to the extent that some states have passed laws making medical supervision compulsory. There are 38 states that have laws requiring or permitting employment of medical inspectors.¹ Actual statistics show that the pupil of today is sturdier, taller, and healthier than his more frequently rachitic parent. This may properly be attributed to health education.

In actual practice, how would such a program embodying all the above factors work out? From a practical point of view, the best idea of this school medical service can be secured from an annual report showing just what was done for the year. Certain items not particularly stressed during the given year would necessarily be omitted.

The *Annual Report* of the Albany Public School System for the year beginning September, 1932, and ending June, 1933, is summed up as follows. The city was arbitrarily divided into 4 districts; cosmopolitan, working class, residential, and high school. Each district was further subdivided into nurse group sections. The latter sections were made up of the individual schools. We may go further and subdivide the schools into the grades and the grades

* An analysis based on the Annual Report of the Department of Medical Supervision of the Albany Public Schools for the year 1932-1933.

into the individual pupils. With such a system we may realize how easy it is to note a particular phase of health referable to any pupil, any class, any school, or group of schools, in any district or in the city as a whole.

VISIBLE RECORDS

A visible and signalled health card system is used.² Different colored signals are used. The red signal signifies that a defect has been notified but not placed under treatment; blue that the defect has not been notified; yellow that the defect has been placed under treatment; purple that the defect has been operated on; and the black and white striped that the defect has been cured. There is a constant campaign to "Keep out of the red," red being the danger signals of untreated defects.

PERIODIC HEALTH EXAMINATIONS

Every pupil is examined once a year. Pupils will grow up with this periodic health examination habit which will continue throughout the remainder of their lives.

DEFECTS FOUND

The average for all the schools was 72 per cent, 8 per cent less than 2 years ago. Also 2 years ago there were almost $1\frac{1}{2}$ defects per pupil while this year there were about $\frac{2}{3}$ defects per pupil.

The schools in the cosmopolitan and working class sections of the city had the highest percentage of defects, the average being about 80 per cent. In the residential sections the defects found dropped to about 65 per cent. In the high schools the average was 60 per cent.

NUTRITION

All the pupils were weighed and measured; malnutrition was found in 672, or 4.6 per cent. The question of nourishment, particularly undernourish-

ment, has been stressed during these periods of depression. It may be said that the cases of undernourishment found were readily taken care of by the City Welfare Department, the schools themselves, or various private welfare agencies. The actual number of undernourished cases was at no time much higher than is found under normal conditions.

Nearly all schools had milk supplied either from private or donated funds. As a matter of fact, of the 672 cases of malnutrition, 419 were undernourished and 253 obese. Albany's percentage of undernourished is low in comparison with most other cities of its size, many having malnutrition rates as high as 20 and 30 per cent. The curve for malnutrition, as noted on Graph I, shows that no definite area of the city is particularly involved.

In estimating malnutrition the cases found were based on individual examination of the pupil rather than an attempt to standardize a child with some age, height, weight table. This is in accord with the State Department of Education and the Commissioner of Education of the U. S. Department of the Interior. The latter says: "No two children are alike and no two children can be made to follow one pattern of growth. The child should be compared with himself and not with the average child."³ In the open air classes, which are the only ones in which age, height, weight tables are kept, each child has his own chart and compares only with himself.

TEETH

This curve (Graph I) showed that 43.5 per cent of the pupils had teeth defects. This is 7 per cent less than 2 years ago.

The 2 school dentists examined and cared for 1,449 needy pupils. Fifteen appointments are made for each dentist each morning from 1 nurse group of

GRAPH I

schools. The 2 dental hygienists examined 1,759 pupils and gave prophylaxis (cleanings) to 2,621.

EYES

All the pupils had their eyes tested. There were 2,834 pupils (20.3 per cent) with eye defects (Graph I). This compares favorably with most other communities. Most authorities find 1 in every 5 have a visual defect. The local ophthalmologists disclosed that over 90 per cent of the pupils referred to them for visual defects required care and attention.

The percentages of pupils with abnormal vision showed that most of the visual defects are of the 20/30 type, this being the least manifestation of visual error and the most remedial.

Formerly the eyes had been tested by means of the Snellen Chart under varied conditions of illumination in the different schools. An average of 4½ minutes was required for each pupil. With our newly devised eye test cabinet, an average of only 1½ minutes was required. This cabinet has proper illumination. It is placed on the nurse's desk which she does not have to leave

GRAPH II

at any time during the examinations. Teachers and pupils aid in a monitor system.

A survey disclosed 53 possible sight saving candidates for all grades. Of these, 36 were in the junior high school grades. These had 20/70 or worse in both eyes. Adjustable desks and seats, special large type typewriters, large type texts and other new equipment were supplied the sight saving classes.

EARS

Audiometer hearing tests were given to all pupils from the third grade through senior high school. The tremendous economic importance, not only to the health of the pupils but also as far as teaching and education are concerned, of these hearing surveys and treatment of defects found may readily be seen.

The 4A tests and retests were done by the nurses. The 2A tests were done by the school physicians.

Pupils in each classroom were divided into 4 groups. Those with normal loss of hearing, from 0 to 9 per cent, were placed in the rear of the classroom. Pupils with borderline defects ranging from 10 to 15 per cent were

placed next in front. Those having definite defective hearing of 16 per cent or over were placed still further front, while the front now contained those who had the poorest hearing.

There are 2 lip reading classes, 1 in the night schools and 1 held Saturday mornings for high school pupils.

Each teacher was given a list of her pupils showing how to group and seat them advantageously with reference to their hearing. A similar classification was arranged for vision.

THROAT AND GLANDS

Graph II shows that 8.8 per cent of the pupils have throat conditions which are essentially affected tonsils. This is 7 per cent less than 2 years ago. Two and two-tenths per cent have gland defects, essentially cervical or neck glands due to affections of the tonsils.

ORTHOPEDIC

Two and four-tenths per cent of the children have orthopedic defects (Graph II). These are chiefly flat feet, round shoulders, and other postural defects.

There are 2 teachers in charge of the orthopedic classes in the Child's Hospital. In addition there are 2

teachers giving home, other hospital, and bedside teaching. A swimming class for crippled children is being formed with the aid of Dr. Walter Craig, State Orthopedist.

HEART

A survey was made in all the schools to find how many heart cases there were, what types, and what should be done medically and from the school standpoint. It must be remembered that heart affections still cause more deaths than any other single condition, and that the percentage of people dying from heart conditions is increasing. Proper preventive procedures may be carried out so as to avoid more serious disabling consequences and to permit each pupil to be better fitted for his school work. The survey was made in accordance with the standards established by the American Heart Association.⁴ The routine for each pupil included at least a complete history, physical examination, cardiac examination, blood pressure, spirometer test, and cardiac functional test.

The survey disclosed 122 cardiac cases or 0.6½ per cent of the pupils, 55 boys and 67 girls. The causes in

order of frequency were rheumatism, tonsillitis, congenital, scarlet fever, whooping cough, chorea, measles, influenza, bronchial asthma, and too rapid growth.

Three-fourths had mitral regurgitation, while almost one-fourth had the more serious stenosis of the valve. There was 1 case of regurgitation of the aortic valve and 1 case of general endocarditis.

In order to classify these cases as to functional ability so as to determine what the child could or could not do physically, each was given a cardiac functional test. Some were permitted mild physical exercise while others were excluded entirely from physical or manual training classes. The survey for functional ability showed that 46 per cent of the cardiac cases had to have their activities slightly limited; 35 per cent could carry on the ordinary activities, being careful to avoid undue strain. This is important in that it shows that not every individual with a heart condition must be made an invalid. These latter cases, however, need repeated examinations and observation. Six per cent of the cardiac cases require considerable curtailment

GRAPH III

of activities. There were no children in the schools with organic heart disease who were unable to carry on any activities without discomfort as such cases would be confined either to the home or to the hospital. Seven per cent of the cardiac cases were possible cases of heart disease, that is, pupils who showed abnormal signs or symptoms referable to the heart but in whom the diagnosis of heart disease was uncertain. There were 6 per cent of the cardiac cases designated as having potential heart disease, whom it was advisable to follow because of the presence or history of a causative factor which might bring about heart disease. The distribution of heart cases was approximately the same for all sections of the city.

NOSE, DERMATOLOGICAL, ABDOMINAL, PULMONARY

All these amounted to less than 1 per cent.

DEFECTS NOTIFIED

Ninety-two per cent of the defects found were notified. This is in keeping with the general program of prevention where the slightest possible defect may result in most serious consequences so that all parents as nearly as possible are notified of defects found.

DEFECTS TREATED

This curve (Graph III) showed that 36.6 per cent of the defects were treated, or 3 per cent more than 2 years ago. This is the most important chart. The number of children examined, the number of defects notified, and other health procedures are of little value unless the conditions found are actually treated or placed under observation by the private physician. The more defects taken care of the better fitted are the children to pursue their studies.

The highest percentage of defects treated, 85 per cent, was in the Senior

High School. The schools in the residential sections were next; then the cosmopolitan and working class sections. The remaining schools ranked between 20 per cent and 50 per cent.

ABSENCES

Seven per cent of the pupils were absent for all reasons during the past school year; 3.9 per cent of them for illness.

The highest percentages of absence due to illness as compared to the total absences were in the residential sections where 1 school had as high as 95 per cent. The high percentage of absence due to illness in the residential sections may be due to the fact that the children are kept out of school for lesser ailments. As has already been noted, the percentage of pupils with defects treated is also comparatively high in the residential sections.

The most common conditions for which pupils came to the nurses were, in order of frequency: colds, headaches, stomach and other abdominal complaints, toothaches, skin conditions and injuries. Colds account for about one-half of all absences for illness.⁵

ANTIDIPHTHERIA CAMPAIGN

Schick tests disclosed that almost 25 per cent of the children were naturally immune to diphtheria and required no inoculations: 74 per cent are inoculated against diphtheria. Pupils are urged to go to their private physicians for immunization.

HEALTH EDUCATION PROGRAM

A health education program, aside from the periodic health examinations and the instruction with reference to prevention of disease and caring for defects found, included the distribution of health bulletins on hearing, vision, measles, diphtheria, periodic health examination, whooping cough, first aid, the use of the audiometer, etc. This

program also included teaching of health habits through individual contacts with pupils, teachers, and parents.

SANITARY SURVEY

The newer schools have modern up-to-date methods of sanitation and in the older type of school buildings the conditions are kept as satisfactory as possible.

TEACHERS EXAMINED

There were 20 teachers examined. Low blood pressure and poor vision constituted the main group of physical defects among the teachers.

WORKING PAPER EXAMINATIONS

There were 1,141 examinations made; 1,069 children were granted unlimited permits; 20 limited permits; and 52 were refused or had their permits deferred.

RINGWORM

Two years of bacteriological investigation to substantiate our clinical findings have been completed by Dr. Harold Feigenbaum, in charge of Chemical Laboratories at Rensselaer Polytechnic Institute. A powder containing 80 per cent boric acid and 20 per cent sodium thiosulphate is still being successfully used. The less practical footbaths of 15 per cent sodium thiosulphate have been discontinued.⁶ In a recent article⁷ it was noted that most schools and health centers in the country have adopted fungicidal procedures similar to those used in the Albany public schools.

TUBERCULOSIS

Conferences were had with the Albany County Medical Society urging them to initiate an antituberculosis campaign in the schools. The Vaughan Plan was recommended so that the pupils could go to their private physicians for tests and examinations.

SUMMARY

The duties of the school medical staff are twofold, medical and educational,⁸ and these are mostly interchangeable.

The medical phase of the work is one entirely of preventive medicine. The pupils receive annual periodic health examinations by the private or school physicians. An attempt is made to have all defects corrected by the private physicians and to have all the pupils vaccinated against smallpox and inoculated against diphtheria. Campaigns are constantly carried on to prevent the spread of contagious and communicable diseases. Special examinations and considerations are given to handicapped pupils, to candidates for athletics, and for employment certificates. Employees of the school are examined. Other than for emergent first aid—absolutely no therapy is given.

The educational part of the program calls for health instruction, particularly individual or in small groups. Important matters considered are the periodic health examinations and correction of defects, care of the various parts of the body, and sanitation and hygiene. The school is made to fit the pupil as much as possible from the health standpoint. A healthy child, a healthy teacher, and a healthy school environment is the ideal combination sought.

The Use of Laymen in Official Public Health Nursing Programs*

CITY

J. D. DOWLING, M.D.

Health Officer, Birmingham, Ala.

WE are all prone to say that health is a matter of education. How shall we interpret this rather loosely used phrase? Some regard it as an advertising of the health department in order to create a favorable attitude toward it. Others look upon it as an accumulation of academic data on health stored away but little used. Still others consider that each individual in the community must play his part in changing attitudes and ways of living to those which make for health if health is really a matter of education.

"The informed citizen takes an advanced course in public affairs by becoming an educator himself in his personal contacts and through local civic associations," Courtenay Dinwiddie of the Commonwealth Fund says in commenting on public health and public opinion.

It is interesting to scan the history of the use of lay people and the influences which have given impetus to a fuller appreciation of their part in the program for community health, more particularly as they relate to public health nursing.

Some of us have had an opportunity in certain communities to observe a shifting of responsibility for home care of the sick from the non-professional to

the professional groups. Then, we later may have had an opportunity to observe a slowly dawning realization of the lost values in the assumption of the whole program by the professional group and a consequent revision of program which includes both professional and non-professional, resulting in a nice division of responsibility.

Public health nursing had its inception in visiting nursing. Visiting nursing has had a strong emotional appeal to lay people. The care of the sick poor in their homes by visiting nurse organizations was sponsored by lay groups. Public spirited citizens fostered the work of visiting nurses until the community was convinced that public moneys should be used for the preventive aspects of the visiting nurse service. Since the lay boards of these organizations were often particularly concerned with the raising of funds, interest in the work under the official agencies sometimes lapsed when there was no longer need for the type of service formerly given. Perhaps a further cause of the non-use of lay groups in official agencies was an attitude of resentment of any "interference" on the part of some of the older staff members. This attitude reacted detrimentally upon any sporadic interest which might have been evidenced by any lay person or group.

Public health workers have been interested in the development of a broad

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 11, 1933.

health program founded on scientific principles, perhaps losing sight of the need for a sound educational program which includes Mr. and Mrs. Everybody in the community. There was an attitude with some of the workers that "this was *our* job and the public depends upon us to do it," and they have been slow to acknowledge the values of service and interest from the non-professional group.

Conditions of the past few years in the public health field have brought us face to face with reality. Municipal treasuries are low; tax payers seek a way out; appropriating bodies are prone to cut their budgets where there will be least pressure from influential political groups. And we have suffered.

Looking back upon the records of health departments as they struggled under the stigma of city hall influence, there is little wonder that it was not desirable to invite the close scrutiny of the community's citizens. There is little wonder, too, that it was in the unofficial public health nursing organizations that high standards of work were set.

With the development of earnestness of purpose, of a real desire to render to the public, nursing service of quality in official public health nursing organizations, we now want to be understood; we now know the need of an informed public; we now know that an understanding public means protection of the thing we have builded. Too, we know the inherent possibilities for a finer understanding and appreciation of the rapidly growing official nursing services. So much for a story of changing attitudes and widening perspectives.

Now that we have discovered that we need each other, how may we create interest in the lay groups and then direct it toward useful ends? Each city will find, in various established groups, a lively sympathy and curiosity about

what is going on in the health field. What we would do, is to reach this fine spirit of helpfulness, organize, inform, and direct it into regular, orderly channels which are so much in need of help.

The Federated Clubs and Parent Teacher Associations have health sections. They may serve as rallying points. The Chamber of Commerce has its public health committee; Junior Leagues are particularly helpful aides; church groups find certain phases of the service challenging. One city reports a continuous diphtheria prevention campaign carried on by the American Legion. The luncheon clubs, Rotary, Kiwanis, Civitan and others have projects closely allied to the field of public health nursing.

When interest is aroused, latent ability for leadership must be detected, and scattered interest crystallized into action. I like to think of the logical stages through which the organization of lay groups moves: (1) There is participation in a broad educational program, learning something of the community's needs. (2) We would expect participation as a volunteer in some of the activities which are set up to meet these needs. One of the recommendations of the Welfare Committee of the Junior Leagues relating to volunteer service states that "one of the ultimate objectives of volunteer service should be to qualify for intelligent board membership in welfare agencies." (3) We would expect a selection of leaders to be made from this group of volunteers to act as members of an advisory committee. In this committee would be developed a broad social vision which it will, little by little, interpret to its community.

Let us illustrate the steps through which a city bureau may go in order to secure lay interest and direct the activities which are the logical outcomes of such interest.

A department of health in one city without a visiting nurse organization, realizing its need for greater lay interest in the whole public health program, found a real desire for fuller knowledge of what was done to protect the community's health in the District Health Chairman of the Federation of Women's Clubs. A plan was laid for monthly meetings at the department headquarters, bringing together the health chairmen of some 60 local clubs for study of local problems. They learned of the activities carried on in their community to meet these problems and of some of the pressing needs as yet unmet.

At the end of the first year's study they sponsored a week's Institute for lay groups. This was conducted by Evelyn K. Davis, Assistant Director of the National Organization for Public Health Nursing. The theme of the institute was "How may members of non-professional or lay groups prepare themselves to participate intelligently and effectively in a program for the promotion of community health and welfare?" The response to this institute was gratifying, indeed.

The department of health has continued to carry on the education of this changing group of health chairmen. The health chairmen have reported on the subject discussed at each meeting to their individual clubs for the 3 years since the initiation of the plan, thus disseminating to a larger group knowledge of the organization and activities of their department of health.

Special interests have developed, some in public health nursing. Sometimes it has been the appeal of a Mothers' Day program, or the story of diphtheria prevention which has stirred the desire to take an active part.

These same women have sponsored an annual publicity campaign for Mothers' Day and have fostered the organization of classes for expectant

mothers in several of the health centers of this city.

The summer round-up chairmen of the Parent Teachers' Association have had a similar series of demonstrations, resulting in an intensive successful house-to-house canvass for diphtheria prevention, in conjunction with their own canvass for school entrants.

Negro groups are as alert to serve their race as are the white people.

The organization of an advisory committee from *below upward* is sounder than from *above downward*, according to Dr. H. S. Mustard, in his report of the Commonwealth Fund Demonstration in Rutherford County, Tenn. He says "It is wrong to assume that a leader is necessarily interested in the health program." He advocates the organization of local committees along specific lines. These committees may be kept reasonably busy supplying volunteer service. The busier they are the more they assume responsibility.

The public health nursing field is technical and at first glance it may seem that only highly trained professional workers could carry on the program, but there are many places for the non-nurse. It is an ancient calling, this service to people, and not a new profession. Weighing and measuring children is work most women love. Transporting patients to clinic, making garments for new-born babes, taking records for the doctor in clinics, making dressings and supplies, or entertaining youngsters while their mothers attend classes at health centers, are all activities in which volunteers may engage and find joy in doing.

Do all those who signify a willingness to serve maintain their interest and continue to grow with the organization? Not unless there is careful selection of volunteers and a definite plan for their instruction and the development of leadership. Let us analyze the motives underlying an interest in

public health or in public health nursing. It may be just a hobby; the person may be an "uplifter" or a "lady bountiful"; or may find in this activity an outlet for a pent-up spirit; or may have genuine interest in social progress and social welfare. If it is a genuine interest in social progress and welfare, much effort will be saved in the sifting process.

The Junior League has carefully planned a placement service for volunteers, fitting the worker into the job which is most challenging to that individual. It is advocated, too, that definite instruction with demonstrations should precede the initiation of the volunteer into any activity. We provide for growth and refresher courses for our professional staffs, and often let the interest and service of the volunteer lag because of lack of cultivation.

The liabilities and problems of volunteer service, such as irregularity and lack of continuity of service, should diminish with careful selection, placement, training and supervision. The advantages of volunteer service, such as more interest and better understanding of the work of the organization, the saving of nurses' time, the economic value in actual service rendered, the publicity value, more than offset the disadvantages.

A few municipal public health nursing bureaus have reached the point of organization of an advisory committee of lay people which assumes some responsibility for a continuing and growing community nursing service. St. Louis, Mo., and Syracuse, N. Y., each reports lay committees on nursing service whose function is the interpreting of the service to the community. Some other cities, such as Nashville,

Tenn., Charlotte, N. C., and Savannah, Ga., have joined the forces of all agencies, public and private, doing public health nursing and are affiliated under the official health department. The policies of the organization are determined by a board made up of representatives from the several contributing and interested agencies. Such a coöperative arrangement should have certain distinct advantages. Bertha O. Yenicek, Superintendent of the Municipal Visiting Nurses of St. Louis, comments on the advantages of a lay advisory committee thus:

Its advice and counsel are just as necessary for the development of the program, policies, and standards of the official agency as in the private agency—indeed more so, because of the complexities of city governmental administration. A lay advisory committee may be quite important also in securing an adequate appropriation from the city's committee on finance for the public health agency.

We conclude then that our aims in using laymen in our public health nursing programs are these:

1. To secure intelligent public response.
2. To secure and utilize volunteer effort.
3. To organize advisory committees who will aid in guiding public opinion and in advocating appropriation of public funds with intelligence and vigor, and who will aid in setting and maintaining the highest standards of personnel and of work.

What are our results thus far? We have builded through the years a stronger partnership between the professional and non-professional groups. We are directed toward organization of specific groups of lay citizens dedicated to the fostering of the purposes of the public health nursing bureaus of our official agencies with a consequent strengthening of all public health nursing in our communities.

DISCUSSION *

PEARL McIVER, R.N., F.A.P.H.A.

*Special Nurse in Investigation of Public Health Methods,
U. S. Public Health Service, Washington, D. C.*

I WAS especially interested in Dr. Dowling's statement relative to the attitude of the present-day official agency which is engaged in public health nursing. He said: "With the development of an earnestness of purpose and a real desire to render public health nursing service of quality, we now want to be understood; we know that an understanding public means protection of the thing we have builded."

I think Dr. Dowling is quite right and I believe that any department which has a thoroughly efficient service, or is rendering the best possible service for the expenditure which is available, *wants* the public to know what it is doing. One is always suspicious of a department or an individual who is "afraid of interference" from an advisory committee, or too close contact with a nonofficial organization. One usually finds that the department, or the individual who is afraid of interference has not been carrying out the principles which make for quality nursing, and he or she does not want to be found out, or, to use Dr. Dowling's expression, "to be understood."

Dr. Dowling mentioned that the non-official nursing agencies were the ones who originally set the high standards for public health nursing work, and I think we will all agree with him. However, recent studies indicate that the quality of work which is being done by official public health nursing agencies today compares very favorably with that of the nonofficial agencies, and I

wonder if the closer relationship between official and lay groups which is quite evident in various sections of the country, is not one factor in securing that improvement? Official health directors are realizing that they are likely to lose much of the fine organization which they have built up unless there is an informed and intelligent group of citizens ready and willing to promote the interests of their departments.

I liked Dr. Dowling's statement in regard to the three steps which are desirable in promoting the organization of lay groups. I believe that these three steps are quite essential to successful lay participation in the health program. I wonder if the apparent failure, or perhaps I should say, the doubtful value, of some volunteer programs is not due to the fact that we are expecting service from folks who have had little opportunity to know what we are trying to do, and we have made little effort to help them to become acquainted with our work. Then too, from the other standpoint, sometimes we find an enthusiastic citizen who wants to "help on some health committee," and yet when the health department calls on her for service she begins to make excuses, or, worse yet, she fails to do what she has promised to do. In other words, there are lay helpers who want to take the last step first and they are not willing to take the first two.

I am primarily interested in the rural field and I have been trying to picture how the rural health department can provide for these three steps in the utilization of lay workers. As Mrs. Trawick has stated many rural communities have very few, if any com-

* This discussion applies to the paper by Mrs. Arch Trawick in July Journal as well as to Dr. Dowling's paper.

munity organizations through which the health department can work. It is often necessary for the health department to help to promote organization before it can obtain concerted action from the community. One of the county nurses whom I have had the privilege to observe during the past year has made excellent use of lay groups and yet she found practically no organizations present when she began her work in that county. She began by organizing Mothers' Clubs in the various communities, and while the lessons were largely concerned with infant and maternal care, the facilities for general home and community sanitation were always discussed. Following the formal class periods, the nurse continued to use the club members as her committee members and she called on them for volunteer service very frequently.

For instance, a midwife came to the office one morning to report that she had just delivered a young mother whose husband had deserted her, and that the mother was alone, had no food in the house, no clothing for the baby, and no one to take care of her. No doubt every public health nurse who worked in a county which had little or no organized welfare work, met similar situations very frequently last year, but I doubt if many of them handled the situation more effectively than this nurse. She had her day's work planned so she left a little earlier than usual and stopped by to see the patient and to verify the midwife's story. Then she went directly to the leader of the Mothers' Club in that community and presented the facts to her. She said:

I'll be busy until evening, but I will call in to see Mrs. Blank when I come home to-night and when I get there, I want to find her well cared for. Here is a card which you may take to the county poormaster, and he will give you a grocery order for her; and

I am sure I can rely on you women to do the rest.

When she returned to the patient that evening, this is what she found. Six women had been in and cleaned the house thoroughly. One of the men in the neighborhood had gone to town on his mule and had got the grocery order from the poormaster, and the women had left a supply of food all cooked and ready for the mother and her other two children. The women had brought one of their "Club Layettes" for the new baby, and he was clean and asleep in an improvised baby bed. And, by the way, those layettes which were prepared by the clubs were too clever for words! The majority of the club members were very poor and while the preparation of the layettes was more or less a social activity for the group, the purchase of materials was another matter. The layettes were made entirely from used sugar and flour sacks. The sacks were first washed and usually bleached, but sometimes the original Gold Medal or Pillsbury's Best sign was still very much in evidence. All of the garments were cut according to the Maternity Center patterns though, and very neatly made, and you would be surprised to see what nice soft little garments can be made from sugar sacks.

In addition to the above service, the nurse found that the women had made out a schedule and one of them had agreed to come each day to give the mother the necessary care. Through their classes, they had been taught how to care for a mother and her baby; they knew how to recognize abnormal symptoms, and they knew how to get in touch with the nurse if anything appeared to need attention. Thus it was not necessary for the nurse to return to this home for a week and in the meantime she could be reasonably sure that the woman and her baby were getting the necessary care and attention.

That nurse has taken the first two steps in the organization of health committees. She first taught them something about their own and their community's health needs and what to do about them, then she gave them ample opportunity to practise what they had learned through volunteer service. Incidentally, when the county officials decided to do away with the health department a few months later, as an economy measure, these women and many others, made such a protest that the idea was soon abandoned and the health department was retained, in spite of the depression.

Mrs. Trawick mentioned the conflicts and unnecessary expenditures which sometimes occur because national boards or agencies, in promoting non-official health work in local communities insist upon independent action from their groups. We have all experienced some of those difficulties at times. One point I wish to make is that the official agency sometimes forgets that any agency which depends upon popular public support has to be able to point to certain definite projects as its own. On the other hand, any lay organization or nonofficial health agency which embarks upon a health program before trying to harmonize its plans with those of the existing official health agency is violating the most fundamental principles of good organization. A functioning advisory health council, made up of representatives of all local agencies and individuals who are interested in health promotion, will usu-

ally solve the problem. But the council must be "non-sectarian." It must be a county health council, not a tuberculosis, a Red Cross or a child welfare council, although each of those organizations should be well represented.

Mrs. Trawick also mentioned that it was difficult for her to differentiate between the services which her organizations rendered to the public health nursing service and those rendered to other public health services. I quite agree with her and I would like to ask—Do we want to differentiate? I would like to emphasize that the nurses are not the only workers in a health department who are benefitted by lay advice and service. In a county health department such as Mrs. Trawick has described, I favor an advisory health council which serves the entire health department. The same persons who are interested in the nursing service are interested in clean milk, safe water, the prevention of diphtheria, and hospital facilities for tuberculosis patients. After all, all of these are public health nursing problems too. Just as an intelligent lay advisory service has improved the quality of the nursing service, so it can influence and stimulate a better quality of medical and sanitation service.

The health officer, the sanitary officer, and the nurse should all participate in the county health council meetings, from time to time. The members of the council should be equally familiar with the work of each.

Qualifications and Training of Local Health Officers^{*}

THOMAS PARRAN, JR., M.D., F.A.P.H.A., AND
DON M. GRISWOLD, M.D., DR.P.H., F.A.P.H.A.
State Department of Health, Albany, N. Y.

IT has been more than 150 years since Johann Peter Frank, in his work on Medical Polity, first presented the idea of "scientific medical police"; and the first suggestion that university degrees be conferred in "state medicine" was made nearly 70 years ago by Henry Wildbore Rumsey. Yet there are still many states in which there are no legal requirements that a local health officer have qualifications other than those of a general practitioner of medicine. In some states not even this is required. It is obvious that for the modern practice of public health, involving the application of knowledge from many and varying sciences, special training is necessary. "An incompetent physician endangers the health of the patient whom he attends; the incompetent health officer endangers the health of his entire community."

Students of the problem agree that local health officers need special qualifications in addition to those required for the general practice of medicine. This need has been discussed repeatedly in the Association and committees have studied it for long years. The essential facts are clear, but we need action—legal action—which will require that every person holding a responsible administrative public health position shall possess certain minimum qualifications

specified in law or in state health regulations.

As early as 1907 Biggs proposed definite requirements for the eligibility of physicians as health officials. Sir William Osler in one of his last public addresses said, "The health officer should have special training in sanitary sciences, and special courses leading to diplomas in public health should be given in the medical schools. Were the health of the people made a question of public and not of party policy, only a skilled expert could possibly be appointed as a public officer, not, as is now too often the case, the man with political pull."

New York State has been working along these lines for 20 years and has made some progress. When the Public Health Council was established in 1913, it was given authority to prescribe qualifications for local health officers and certain other public health personnel. The following year standards were established for local health officers. The State Department of Health, coöperating with a number of medical schools, offered extension courses and short residence courses in public health. Because of the great variation in the size of municipalities, ranging from the small rural towns to the large cities, any one set of standards would be too high for the one, or too low for the other.

In succeeding years laws were added

^{*} Read at a Special Session of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

which gave the Public Health Council authority to prescribe qualifications for directors of divisions in the State Department of Health, district state health officers, public health nurses, bacteriologists-in-charge of laboratories, and, more recently, pathologists. These requirements have been implemented by other provisions of law which require:

1. That approval shall not be issued to a laboratory unless the director possesses the qualifications established by the Public Health Council.

2. That county health commissioners shall devote their full time to the duties of their office and shall possess such qualifications for office as shall have been approved by the Public Health Council.

3. That health officers appointed after 1931 in cities of more than 50,000 population shall devote their full time to the duties of their office.

4. That "notwithstanding the provisions of any general or local law or charter a physician who is qualified by the Public Health Council shall be eligible for appointment as health officer.

This last provision invalidates any restrictive provisions of city charters and other laws concerning qualifications such as residence, length of practice in the municipality, or otherwise. The enforcement of qualifications is aided also by the authority of the State Department of Health to grant or withhold state aid. State aid to county departments of health and other local health activities, may be withheld if the standards of service, including the qualifications of the health personnel, do not meet the prescribed standards. Further control is given by state authority to remove from office an unqualified health officer.

In 1930 this whole subject was reviewed by the New York State Health Commission and further enactments were recommended to require varying standards for local health officers, depending upon the responsibility of their position and the area served. Local health officers in New York State may

be grouped, broadly, into two classes: (1) the full-time health officer, serving cities of more than 50,000 population, the full-time county commissioners of health and the district state health officers; (2) local health officers of smaller jurisdictions.

A further recommendation of the State Health Commission that all counties be required to establish county departments of health, with full-time personnel, has not yet been enacted, and we have only 5 such departments in our 57 counties. The remaining counties are served by a state supervisory staff of 14 district state health officers, state district nurses, sanitary engineers and milk sanitarians, and by local health officers in our towns and villages.

Excluding county units and cities over 50,000 population, there are 1,201 local health districts. By the appointment of one health officer to serve more than one town, village, or consolidated district, these 1,201 districts are served by about 800 health officers. A minimum of \$.15 per capita is paid to these health officers, up to \$1,200 per annum. In addition, fees for special services frequently increase this income considerably.

One-fourth of these local health districts have a population of less than 1,000; one-third have populations between 1,000 and 2,000; another one-third have populations between 2,000 and 8,000; and only 8 per cent have populations between 8,000 and 50,000. Eighty-two per cent of these local jurisdictions have populations less than 4,000 and pay a minimum salary of less than \$600 a year. These men are practising physicians and frequently the health officer is the only physician in the town or small village. The requirement of special qualifications for this group obviously cannot be so stringent as for the full-time position.

After intensive study, conference with local health officers, medical educators

and others, the Public Health Council in May, 1932, completely revised its qualifications for local health officers. Two classes were established, the first to include district state health officers and health officers of counties and of cities of more than 50,000 population, and the second to include smaller municipalities. A requirement for every health officer is that "he shall be licensed or eligible for examination for license to practise medicine in New York State."

The requirements are:

Regulation 5. Qualifications, Grade I. The qualifications for health officers in Grade I shall be practical experience and/or special training and education in public health, consisting of:

(a) Not less than 4 years of full-time experience in a responsible public health position. Or,

(b) Not less than 2 years of full-time experience in a responsible public health position and the completion of a course in public health approved by the public health council of at least 1 scholastic year in residence. Or,

(c) A combination of part-time or full-time experience in public health with special training which combination in the opinion of the council is the equivalent of either of the above qualifications.

Regulation 6. Qualifications, Grade II. The qualifications for health officers in Grade II shall be practical experience and/or special training and education in public health, consisting of:

(a) Four years' part-time experience and prior to June 1, 1932, the completion of a course in public health approved by the public health council.

(b) The completion of a course in public health, of less than 1 scholastic year in residence, approved by the public health council as qualifying for this grade subsequent to June 1, 1932.

(c) The completion of an undergraduate course in public health approved by the public health council as qualifying for this grade.

(d) Other practical experience and/or special training and education in public health work which in the opinion of the council is the equivalent of any of the above qualifications:

Provided, that under special circumstances specified in writing by the local board of health or other appointing power or by the

proposed health officer, the public health council may waive the requirements for a health officer in Grade II as to any proposed appointment, *such waiver to be valid only for the term of the proposed appointment.*

Additional regulations provide that any physician, or any local appointing officer, may submit to the Council the qualifications of a physician for opinion as to whether or not they meet prescribed standards; that such person may be required to take "such written, oral or practical examinations in public health as the Council may direct"; and that the Council may maintain lists of persons who have submitted satisfactory evidence that they possess the qualifications for either of the two grades.

Under Regulation 5(b), courses in public health at Johns Hopkins and Harvard have been approved. It should be noted that for Grade I a minimum of 2 years' experience is required in addition to an approved public health course.

For Grade II two separate types of courses will qualify. First, a "short course" of less than 1 scholastic year. This course is being given by the State Department of Health in coöperation with the Albany Medical School under the direction of one of us who is also in charge of teaching public health to undergraduates. This extension course is designed to qualify physicians now in practice and is an elaboration of previous but less extensive courses conducted in former years by the state in coöperation with various medical schools. In order to meet the needs of the health officer in the smaller municipalities, who receives a comparatively small income from his health work, a course was devised so that the major part could be accomplished in his office at times available from his practice. The extension course is divided into three parts:

(a) *Assigned readings from texts*—These

include the Public Health Law, Sanitary Code, and State Department of Health publications. There are 20 assignments during the year. After reading the assignment the student refers to a "test of study" and writes answers to questions. Students last year reported an average of 6 hours required to do each of the reading assignments and prepare the "test of study."

(b) *A Conference of 1 day each month with the district state health officer*—At each of these monthly conferences a separate phase of local health work is discussed and the student is coached in the practical application of health requirements and the conduct of health activities. One-half of each conference day is spent in observing and participating in such health activities as: inspection of pasteurizing plants; attendance at clinics for tuberculosis, venereal disease, child hygiene, and mental hygiene; administration of Schick and Mantoux tests; visits to approved laboratories, to sewage disposal and water filtration plants.

(c) *One week in residence at Albany*—This is required after completion of the 20 written assignments and 8 monthly conferences. This residence week is for purposes of review, lectures and demonstrations by a temporary faculty of experts in various public health

and clinical branches and for an examination when necessary to test the candidates' fitness.

About 40 students were graduated last year and approximately 100 will take the course this year.

Realizing that instruction in public health should be given more fully in undergraduate medical courses, the provision (Reg. 6-c) permits qualification for Grade II by an approved undergraduate course in public health. Before standards were established for these courses, conferences were held with deans and professors of preventive medicine in each of the medical schools of the state. A committee from this group of medical educators itself drew up for approval by the Council the minimum requirements which must be met in order to entitle a course to approval.

This has resulted in the stimulation of public health teaching to all undergraduates and, obviously, has resulted

in the advancement of preventive medicine well beyond the immediate advantage of qualifying young physicians for positions as local health officers in our smaller health districts.

The results of our efforts to require minimum qualifications for health officers are summarized in Table I. It will be noted that more than 80 per cent of them will have met prescribed qualifications by the end of this scholastic year. The remainder, to a large extent, are serving under waivers chiefly because no qualified physician is available in the small jurisdictions.

Of interest in the training of other public health personnel, but not appropriate to the present title, are the programs of the State Department of Health for the training of public health nurses, operators of water purification and sewage treatment plants, operators of milk pasteurizing plants, bacteriologists, and other health personnel.

In summary, I may say that our practice has developed along very simple lines. We recognize the need

for a physician to have special training in order to be a satisfactory health officer. Adequate laws have been enacted which require special training. For our full-time positions high standards have been set. Our local health structure admittedly is unsatisfactory in its multiplicity of small units and part-time service. The nature and extent of the training possible naturally is limited by the character of the positions. We have fostered courses and assisted in the conduct of courses designed to provide necessary training. In addition, the courses have been of benefit in giving to a large group of practising physicians a broader concept and a better understanding of public health and preventive medicine. Other states, with more satisfactory local units of government, should be able more readily to enforce high standards. The American Public Health Association can and should take the lead in advancing public health in this country through improving the qualifications of local health officers.

A Measles Year

THERE have been reported to the U.S. Public Health Service by state health officers from January 1 to June 9, 1934, 602,990 cases of measles. By periods of 4 weeks, these have been distributed as follows:

These figures include reports from all states except Nevada. Reports of measles are always incomplete, as it is too often regarded as a mild disease and many cases are not reported.

<i>4 weeks ended</i>	<i>Cases</i>
Jan. 27, 1934	51,498
Feb. 24, 1934	94,984
Mar. 24, 1934	128,505
Apr. 21, 1934	132,389
May 19, 1934	124,923
June 9 (3 weeks)	70,691
Total (23 weeks)	602,990

It is evident from the figures that the epidemic is now subsiding.

PUBLIC HEALTH IN THE FAR WEST

THERE may have been a time when some members of the American Public Health Association would have agreed with Daniel Webster when, as Secretary of State in 1843, he intimated to Dr. Marcus Whitman, of Oregon Trail fame, that the Rocky Mountains formed a natural barrier to the westward progress of civilization. Nevertheless, some degree of public health civilization did reach the West. Whether through spontaneous generation or a series of bitter experiences, or a combination of both, western public health organizations, both official and voluntary, have grown apace.

The West has always had its public health problems, some of them unique. Famine and illness threatened the followers of Brigham Young during their first winter in Utah (1847). Cholera took nearly one-fourth of the population of Sacramento in 1850 and 1851. A peculiar fatal illness resembling typhus, but occurring only on one side of the tributaries of Idaho's Snake River, was known as early as 1873, and first described by Maxey of Boise in 1889.¹ Subsequently, Montana's Bitter Root Valley became the stage for one of the most dramatic episodes in public health, resulting in partial solution of the Rocky Mountain spotted fever problem.

Migratory tuberculosis first became a problem in Colorado and California in the 1850's, and it continues a serious problem in the western and southwestern states today. It is recorded that in 1871 the tuberculosis death rate in one section of California reached 344 per 100,000 population.² The highest tuberculosis death rates known in the United States today are in Arizona, 345.7,³ New Mexico, 302.5,⁴ Colorado, 165.7,⁵ California, 132.6.⁶ In none of these states has the rate of reduction of tuberculosis deaths been equal to that of the registration area since 1900.⁷

Coccidioidal granuloma, now of increasing public health importance, and apparently endemic in western arid sections, was first described by Rixford in San

Francisco in 1893.⁸ Dr. Beatty of Utah, Dean of western state health officers, states that he first saw cases of serious illness following bites by the deer-fly in the late 90's, and repeatedly called it to the attention of the Public Health Service, with the ultimate result that tularemia was identified. Plague was first officially recognized in this country in San Francisco in 1902. Three outbreaks have been recorded in California since then, the last in Los Angeles in 1924. It is endemic among California ground-squirrels, and a circumscribed, fatal epidemic among these squirrels has just occurred in the sparsely populated, eastern portion of Kern County.

Earthquake, fire, and flood, with their accompanying public health aspects, have been frequently known in this section. Shellfish sanitation, sewage disposal, and the sanitation of large irrigated areas have presented difficulties peculiar to the West. Following the pioneers, after preliminary discomforts had been overcome, came the horde of health seekers, easy prey for the cults, an ever-present problem in western public health administration. Cultism and smallpox are inseparable companions on the playgrounds of the West.

Until comparatively recent years, full-time health officers and adequately financed health departments have been few and far between in the West. It is not surprising, therefore, that western public health took some time to develop an *esprit de corps*, and yet developed it vigorously when it did appear. Considering their starting point, it would probably be hard to find any large section of the country which has developed a public health consciousness more rapidly than the West in recent years. In many respects, today's western public health picture is one of the most favorable of any in the nation.

For instance, the State of California has provided a state subsidy for local tuberculosis sanatoria since 1915. At present, 90 per cent of the population of this state has access to tax supported, locally administered tuberculosis sanatoria. Last year's Christmas Seal Sale in California, despite the 4th year of the depression, brought 3.3 cents per capita, and was exceeded only by Pennsylvania and New York.⁹ Outstanding contributions in fundamental research concerning tuberculosis now come each year from Arizona, Colorado, California, and Oregon.

In the past 30 years, the West has contributed important fundamental data to our knowledge of vaccinia, alastrim, botulism, coccidioidal granuloma, plague, spotted fever, mottled enamel, shellfish sanitation, and psittacosis.

Important advances in mental hygiene and the teaching of psychiatry to medical students have been contributed from the University of Colorado Medical School. Excellent public health research is coming from the Hooper Foundation for Medical Research, the laboratories of the California State Department of Public Health, the U. S. Public Health Service laboratories at Hamilton, Mont.; Seattle; San Francisco; and Pasadena, also from the medical schools at the Universities of California, Southern California, Colorado, Oregon, and Stanford. Good courses in public health are being given to undergraduates in the medical schools of the Universities of Colorado, California, Southern California, Oregon, Stanford, and Loma Linda. Splendid courses for public health nurses are offered in the University of California, University of Oregon, and University of Washington.

Los Angeles County is reputed to have one of the best organized health units in the United States. It is to be credited with having retained and supported the same health officer for nearly 20 years. The San Francisco City and County Health Department is one of the country's outstanding examples of successfully combining the public health function with that of hospital administration. For

over 20 years, this department has operated the school health program in the San Francisco public schools. Western cities have entered the U. S. Chamber of Commerce Health Contest in surprising numbers and have made excellent showings.

Since 1928, when the Western Branch of the American Public Health Association was organized, the Western membership of the Association has increased from 125 to nearly 500. In addition, they list well over 1,000 so-called Regional Members who are not necessarily full-time public health workers. It is in recognition of these gratifying public health advances in the West and of the success of the Western Branch that the Association this year in holding its 63rd Annual Meeting joins the Western Branch in observing its 5th Annual Meeting in Pasadena, September 3 to 6, inclusive.

The Western Branch, as well as all public health workers of the Pacific Coast, joins in a most cordial invitation to our parent Association and the public health workers of the middle states and the East. We know that we can learn much from them and we hope that owing to differences of climate, endemic diseases, immigration, etc., they will find something of interest in our western country.

POLIOMYELITIS IN CALIFORNIA

WE have been aware for some time that poliomyelitis was unusually prevalent in California, especially in the County and City of Los Angeles. From January to May inclusive, 130 cases have occurred in Los Angeles County and 205 in the City. Orange County comes next with 18 cases, while San Francisco, the largest city in the state, has only had 11. Altogether, there have been 432 cases as follows: January, 25; February, 26; March, 18; April, 36; and May, 327—a total of 432. The jump in May has been something tremendous.

It is needless to add that the situation has caused alarm in other parts and cities of the state, and health officers everywhere are watching the situation and taking every precaution to prevent the spread of the disease.

Nearly 82 per cent of the cases have occurred between the ages 1 and 14, inclusive, the greatest incidence falling between 5 and 9. After the age 14 there is a rapid diminution in the incidence, and those above 35 are practically immune, judging from the figures.

Unfortunately, poliomyelitis still has many secrets which earnest workers all over the world are endeavoring to penetrate, so far without entire success.

While one attack produces lifelong immunity as a rule, the production of artificial immunity is far from having reached a satisfactory and practical state.

In the New York epidemic of 1931, more than 400 control cases were compared with 500 cases who received a serum believed to contain virus-neutralizing substances. The results showed no advantage in favor of the serum treated cases. A similar result was obtained in 1932 by Kramer and Aycock on a smaller number of cases. The serum of those who have recovered from the disease contains a virus-neutralizing substance, and this is true for the majority of adults in urban populations. Prevention has been attempted by the injection of 10-20 c.c. of convalescent serum or parental whole blood, with apparently good results. However, the same report shows that of 2,200 persons not treated, only 31 developed the disease. On the authority of Park, it may be stated that no safe and reliable method of active immunization in man has been found. Different methods have been successful in monkeys, but none has proved sufficiently safe and effective to warrant its application to man.

A SAD MILESTONE IN SANITARY ENGINEERING PROGRESS

IN almost every era of real progress in civilization a few individuals are born who carry on the major activities which distinguish that era. Such an individual, during the advance of sanitary engineering practice in the past 50 years, was George W. Fuller. His death on June 15, 1934, in New York City, at the age of 65, marks the passing of one who had probably more to do with the technical development and the public stimulation in the installation of municipal sanitary devices than almost any man in this country.

Of ancient English ancestry, he was born at Franklin, Mass., a state which has given to this country a long line of distinguished sanitarians. By heredity and by training he was equipped to perform a timely task in the sanitary field.

Educated at the Massachusetts Institute of Technology, he supplemented his training at the University of Berlin and in the private office of Piefke, engineer of the Berlin Water Works. For 5 years thereafter, he had the advantage of contact with some of the most distinguished sanitary leaders in this country at the Massachusetts State Board of Health and at the Lawrence Experiment station.

Beginning in 1895, he conducted the important water filtration experiments at Louisville and later at Cincinnati. The results of these studies established many of the basic principles adopted in the treatment of water supply from that day to this. During the World War he was a member of a sanitary committee at Washington regulating the engineering planning and sanitation of the various Army

George W. Fuller

camps in this country. As consulting engineer to the U. S. Public Health Service and to the Construction Division of the Army, he was responsible for a considerable part of the practices which resulted in the unprecedented low typhoid fever death rate in the Army camps.

He was professionally and intimately engaged for many years in developing programs for sewerage and water supply systems for the Sanitary District of Chicago, New York City, and over 150 large cities in this country and abroad. He was almost as well known in England, Germany, France, and the Far East as in this country.

In American Public Health Association affairs, he was one of the initiators of and contributed largely to the development and widespread adoption of the Standard Methods of Analyses for Water and Sewage, sponsored by the A.P.H.A. He was probably more responsible than any other individual for the successful publication of the *Manual of Water Works Practice* by the American Water Works Association. The list of society activities with which he was identified is so long that it can hardly be repeated here. He was distinguished, however, for the fact that his interests were not only administrative during his entire lifetime, but that he was closely identified with and always highly stimulated by the desire to develop new technical processes and improvements in existing practice. In the American Public Health Association he had a long career of active participation. In 1914 he was Vice-Chairman of the Sanitary Engineering Section; in 1915, its Chairman; in 1924 an elective councillor; in 1925 and 1926, a member of the Executive Board; in 1927 to 1929, a member of the Governing Council; in 1927 to 1928, Vice-President; 1928 to 1929, President, and in 1933 an Elective Councillor for 2 years.

He was past Vice-President and Director of the American Society of Civil Engineers, Past President of the American Water Works Association, and a member of most of the important technical societies in this country and abroad. At the time of his death he was Chairman of the Engineering Foundation, a research organization of the national engineering societies.

In the midst of his busy existence he produced many valuable articles and three books: *Water Purification at Louisville*, *Sewage Disposal*, and *Solving Sewage Problems*, each of them milestones in the development of sanitary engineering practice in this country.

His loss to the public health profession in enthusiasm, in professional judgment, and in technical wisdom is irremediable.

PUBLIC HEALTH EDUCATION*

IF YOU ARE SO FORTUNATE

as to live west of the Mississippi, and particularly if you live in a mountain or coast state, we hope that you will agree that an unusual opportunity is offered in holding the annual meeting of the A.P.H.A. in Pasadena.

IF YOU ARE HEALTH OFFICER OR ASSOCIATION EXECUTIVE

we hope that you will make every effort to facilitate the presence at Pasadena of any and every member of your staff who has anything to do with planning, preparing, writing, distributing health education material.

IF YOU DO ANYTHING IN HEALTH EDUCATION

planning or preparing material, or doing clerical or mechanical jobs, we hope that train, bus or flivver will bring you to Pasadena.

Wrong Again!—"I note with fiendish glee," writes Dr. W. W. Bauer, "two errors in a single paragraph" in this department under "Education and Reference" in the June, 1934, issue, page 655.

To begin with, I note a most startling title assigned to one of Thurman Rice's sex education pamphlets, to wit. "High Life Goes On and On, For Girls of High School Age." Perhaps it does, but not in the Rice pamphlets. Will you please undo this aspersion on the younger generation? The correct title is "How Life Goes On and On."

Will you also kindly correct the statement that individual pamphlets, priced at 25 cents each, cost \$2.00 per set. The correct price per set is \$1.00.

Of course we know that Dr. Bauer is director of Bureau of Health and Public Instruction, American Medical Association, 535 N. Dearborn St., Chicago, Ill.

School Health Education Institute—Elsewhere appears a detailed announcement of the Health Education Institute to be held at Pasadena, this

year to be devoted to school health education.

We Salute Colombia!—We are delighted to receive a copy of *Salud Y Sanidad*, a publication of Departamento Nacional De Higiene Para La Vulgarizacion Y Propaganda De La Higiene Publica Y Privada, at Bogota. Two cover pages with illustrations in color, and a number of sketches with a touch of humor to make them appealing. We hope that Director Ricardo Bonilla will send copies of his health education material to Pasadena.

Who Will Get the Most at Pasadena?—They will get the most ideas for home use, and the best hunches to try out in their own work who go to Pasadena prepared to squeeze the most from the opportunity.

How about making a list of what you would like to learn?

Could you officially canvass the entire staff for questions to be answered and information to be sought?

Hold a staff meeting to discuss the most important questions on which your

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

department or association wants light?

If, as we hope, several staff members will go to Pasadena could you allocate the questions, placing responsibility for getting what is wanted?

Could you decide in advance upon some of the specialists and other individuals who could be consulted?

Could you select certain meetings in which your questions could be asked in the discussion period?

And, of course, it is to be hoped that you will check over your experiences and your successes, or failures, to decide on what you will tell to those you meet and what you will bring up in certain appropriate sessions of the convention.

All of the above applies as well to all phases of public health and of public health activities.

"Things to Forget"—In "a debunking of some of the good old traditions—based on scientific fact," Dr. W. E. Forsythe says:

Hygiene has been spoken of as the yellow dog in the curriculum pack. There is more truth in the statement than in many ideas which have been promoted as hygiene. Too much of the traditional subject matter of hygiene has rested upon unscientific data. Many personal opinions, half truths, and uncontrolled observations have failed to survive immersions in scientific criticism. Such scrutiny promises well for the future of hygiene, which subject is probably not alone in needing "debunking."

Oracular emanations seem never to be recalled. High sources of dogmatism occasionally should reverse the current, retract former deliveries, admit error, and tell us which of former teachings to forget. Certainly much that has been taught as valid hygiene is now recognized as unhygienic, useless, or of doubtful value, and should be forgotten. There are so many worth-while things to be learned about health that no time should be wasted on that which present-day science does not support.

Followed by debunked samples in *Journal*, National Education Assn., June, 1934, Washington, D. C., and

Journal of Health and Physical Education, March, 1934.

Colloquial Health Teaching—Effective health teaching is done in Jamaica through local types speaking in vernacular. In "A New Way to Treat An Old Disease," we are told of an observation visit to the Kingston Dispensary by Aunt Eliza Bush-Tea. Dead "set against the doctors and their scientific methods" in the diagnosis and treatment of tuberculosis, Aunt Eliza protested that

"Dem doan' know to use Nature's remedies. The Lawd mek 'erbs grow far every ailment He set on mankine. Wat de sense of dese injections and 'ospitals and dem tings. Ef 'im meant fa mans to hab dose t'ings why 'E doan' say so in de Good Book?"

"But Aunt Eliza," Retinella had replied, "why can't we make progress in medicine as well as other things? Look at the development of motor cars and airplanes; you old people didn't dream of them when you were young. Many of the modern inventions have been applied to medical problems, helping the advance of treatment immensely."

The common sense argument won Aunt Eliza whose visit is reported in detail in *Jamaica Public Health*, Kingston, June, 1934.

Bring One Hundred Address Cards—We think you will have use at Pasadena for nearly if not all of a hundred address cards or 3 by 5 inch slips on which have been typewritten your name and full address. (It is surprising how many address cards do not carry the name of the city.)

You will hasten acquaintanceship and facilitate the exchange of ideas and information by offering your card.

And you will use quite a number of the cards at the luncheon discussion-demonstration session of education and publicity helps.

And you will use quite a number of the cards when you examine the displays at "Education and Publicity" headquarters and wish to receive free

copies of many items which will be shown there.

"We Tell the Truth"—A "Public Health Column" has been started for the newspapers of the state by the New Mexico Bureau of Public Health. In a recent issue Dr. Earp said:

It is our intention in this column always to tell the truth. We make mistakes no doubt. Whenever we discover them or they are pointed out to us we shall attempt to correct them. But we do not intend to suppress the truth, because we do not believe that it is in the public interest to do so. Health departments have before now kept quiet about poor health conditions in the fancied interest of a trade with tourists or other visitors. The people suffer and in the long run even the tourist trade suffers from such a policy. Nothing encourages visitors to a health resort so much as to know that there is a health department on the job on whom they can rely for a truthful report.

Many Methods and Many Needs—Opportunities for reaching the people are considerably more varied and more numerous in the smaller cities than in the larger ones, in proportion to the population.

The possibilities for the use of diverse methods and materials are much greater in the smaller than in the larger cities.

The resources which can be found and may be used largely increase as the population decreases from that of the greater to the lesser cities.

Much of this sort of material will be brought up in the discussion-demonstration luncheon of the Public Health Education Section at Pasadena. (Be sure to have plenty of address cards for use at this luncheon meeting.)

Easier Steps Are the Best First Steps—An obvious strategy for cancer education is suggested in *Bulletin* of American Society for the Control of Cancer, 1250 6th Ave., New York, N. Y., June, 1934. Under "Accessibility and Cancer Education":

Among the various types of cancer there exist very different degrees of accessibility. This fact has an extremely important bearing on the success of any educational campaign concerning their detection and treatment.

Inasmuch as cancer of the skin occurs more frequently on exposed areas such as the face or hands it is obviously a relatively easy type to detect in its early stages. It is also easy to reach for any selected type of treatment. We may therefore expect that as educational work progresses the death rate from skin cancer may be materially lowered.

To some degree these arguments apply also to cancer of the mouth, tongue, or lip. In the two former types, however, the patient himself must be held responsible for reporting suspicious symptoms as soon as they are recognized.

Nodules which may be early cancer of the breast can be easily detected by any woman who is intelligent and enlightened enough to adopt the habit of periodically examining her own breast tissue. The word "enlightened" in this instance has a very important connotation. It refers to the unfortunate prudishness which makes some women loath to take an intelligent and impersonal interest in the well-being of their own bodies. This factor is of far more importance among those born before the twentieth or late nineteenth century than it is in those who belong to the younger generation. The latter, thanks to increasing sanity and frankness in dealing with questions of human physiology, are not subject to stupid taboo as are their elders.

This fact is perhaps the greatest single cause for optimism concerning the eventual control of uterine cancer. Only those who understand the difference between normal and abnormal manifestations of uterine activity can be expected to recognize and report the latter for immediate examination and diagnosis. Granted, however, that women in increasing numbers adopt a modern and healthy attitude toward the hygiene of the reproductive organs, the chances of improving the situation as regards mortality from uterine cancer is good.

Much remains to be done for handling other forms of cancer among all classes.

In the meantime, public education had probably better place its major emphasis on cancer which occurs in more accessible locations. In the case of cancer of the skin, lip, tongue, and mouth, the educational material and methods can be simple and direct. In dealing with cancer of the breast and uterus, the influence of the intimate site of the cancer must be considered.

If and when progress in the control of different types has been made we shall have powerful and convincing arguments with which to create public support for the more costly and difficult campaign against internal manifestations of this disease.

Please Do Us a Favor—The editor of this department of the *Journal* solicits the privilege of personally meeting every member of the Public Health Education Section who will be at Pasadena, and every health worker who is concerned with or interested in health education.

Please double the favor by mentioning your name and your connection, if possible presenting a copy of your address card.

We thank you in advance.

What They Want to Know—An editorial in *Hygeia*, May, 1934, on "Health Questions and Answers" discusses the 4,500 letters addressed to *Hygeia* asking questions about health.

Most letters asked more than one question, the average being about 136 questions for each one hundred letters. One letter out of every ten asked, either exclusively or in addition to other questions, about books dealing with health subjects. Questions about books, in fact, led the list of subjects. This was true also in 1932. Next in order of interest, occurring in the proportion of one letter out of every fifteen, were questions about food and diet, while questions about the hair and the scalp came next; these were found in one letter out of eighteen. These two subjects virtually shared second place in 1932, occurring then in one letter out of fifteen.

Other subjects in order of interest related to the bones and joints, mainly arthritis and rheumatism; "beauty" questions; sex, not including birth control or diseases of the reproductive organs; drugs; allergy or sensitization, of interest to hay fever and other sufferers; physical therapy; diseases peculiar to women; and on up to a total of 25 subjects.

Most interesting is the shift in order of interest as detailed in this 2-page edi-

torial. In 1932 drugs occupied 25th place; maternal and infant death was in 7th place, dropping to 18th place in 1933; and so on. Our guess is that the range of subjects treated in *Hygeia* and the nature of the articles had some influence on the changed ranking in the classification of the replies.

Hygeia's correspondence covers the entire United States from coast to coast. The letters originate in homes of all characters; they come from writers with a liberal education as well as from those with almost none. A good general education does not seem to carry with it any guarantee of wisdom in health matters.

The letters prove that America is health-conscious, but they prove also that much remains to be accomplished before America can be said to be intelligently health-conscious. The emphasis on personal appearance, evidenced by the prevalence of questions about hair, scalp and "beauty," as compared to the apparent apathy toward real health problems, which is shown by the infrequency of questions on the more important topics, proves that health instruction on the more important topics, proves that health instruction is a big and important job.

Health Education in the Journal
—To facilitate future reference to mentions of health education we plan to record here what has been published on the subject in previous issues of the *Journal*.

In the June, 1934, issue see two references to education in the editorial on "The Medical Examination of Food Handlers."

The same issue includes:

"Organization of Adult Groups for Health Education," by Mary P. Connolly.

"A Plan to Increase Understanding of Scientific Medicine," by T. J. Edmonds.

Your Headquarters at Pasadena—Please make full use of "Education and Publicity" headquarters in the Municipal Auditorium at Pasadena.

Meet your friends there.

Come there as often as possible to examine the display.

Bring there your questions and your problems.

Be there to share your ideas and experiences with others.

Leave your address cards for mailing to your home addresses numerous useful samples and valuable helps. (*Be sure to learn just how this is done.*)

Have plenty of address cards to hand to those you meet so that they will get clearly who you are and what you do, and may note on the card what they promise to send to you.

EDUCATION AND INFORMATION

"The Care of the Child from One to Six," a selected list of references. *Child Health Bulletin*, 50 W. 50th St., New York, N. Y. May, 1934.

"The Control and Treatment of Cardiac Cases Occurring in School Children," by Dr. W. P. Brown, State Education Dept., Albany, N. Y. 2-page reprint. *Free*.

"Depression Makes Health Inroads" is a letter-size handbill issued by Los Angeles Community Chest.

"The Doctor's Office as a Health Center" is the April, 1934, issue of *Tuberculosis Abstracts*, available through any tuberculosis association. Describes the coöperative plan in Detroit.

"Doctor, What Toothpaste and Mouth Wash Do You Recommend?" leads up to the suggestion of common salt, or precipitated chalk and castile soap. *Health Bulletin*, North Carolina State Board of Health, Raleigh. May, 1934.

"Enjoy Health and Happiness at Dayton's Recreational Centers This Summer" is a large, folded broadside issued by Dayton, Ohio, Council of Social Agencies. Inside is a "treasure map" with a key to locate summer opportunities.

"Health: Diseases, Drugs and Sanitation." Superintendent of Documents, Washington, D. C. *Free*. A classified list of federal government publications.

"Health," Ontario's annual health almanac for 1934, drops all calendar features, continuing the varied miscellany of personal and community health material. "The contents are designed to meet the many inquiries from people throughout the Province." Illustrated; 104 pages. The 1934 edition ran to 80,000 copies. Ontario Dept. of Health, Toronto, Ont.

"Present Guides for Household Buying," a handbook of sources of information which should be useful to hospitals, sanatoria, etc., in making the most of the budget. Ask Department of Agriculture, Washington, D. C., for a copy.

"School Lunches," with recipes to serve 50 children. Bureau of Home Economics, Washington, D. C., 13 pages. *Free*.

The Bureau of Nutrition and Health Education, University of Texas, Austin, offers

. . . a set of 8 colorful posters known as the Every Day Health Series, prepared for use in illustrating lessons on health habits. Each poster has an atmosphere of happiness and action.

"Every Day," at the top is followed by such statements as "Play out of doors," "I drink milk," "I brush my teeth," together with a silhouetted picture.

They are 12 inches high, 17 inches long. Set for 45 cents; 55 cents outside of Texas.

The following have been issued by State Dept. of Health, Albany, N. Y.:

"Every Child Needs Cod Liver Oil." 1 page.

"Milk: A Gilt Edge Investment." 4 pages.

"Constipation." 4 pages.

"The Public Health Nurse and the Work She Does." 11 pages.

"The Division of Laboratories and Research." History and present status; 81 pages; many illustrations; 6 large folded floor plans.

"Protection Against Diphtheria." 4 pages. Factual statements in every day language.

Four reprints from *Hygeia*, American Medical Assn., 535 N. Dearborn St., Chicago, Ill.:

"Cancer: Its Status Today." 8 pages. 10 cents.

"A Child Is To Be Born." 45 pages. 15 cents.

"Feminine Beautification." How—from Cleopatra to Greta Garbo. 11 large pages. 10 cents.

"The Child Who Stutters," by F. B. Brown. 22 pages. Bibliography. 10 cents.

"An Index of Nutritional Status," "Vitamin D Milk," and "The Flavor of Milk" make up recent issues of *National Dairy Council Digest*, Chicago, Ill. Free.

Three summer bulletin board posters are offered by Employer's Mutuals, Wausau, Wis.: on poison ivy, prone resuscitation, and first aid for sunstroke or heat prostration. Free.

"Your Child and the School," by Dr. A. G. Ireland, director of physical and health education, New Jersey State Dept. of Public Instruction. Health News Service, 22 E. 40th St., New York, N. Y. Brief 175-word statements for newspaper use on "Summer visiting," "Summer mishaps," etc. Free.

IDEAS AND INFORMATION

About lettering for posters or displays, says *Michigan Public Health*, Lansing (April, 1934):

Letters should never be so unusual or fantastic as to divert the attention of the reader from the thought itself. Tilted devices or ornamental letters often obstruct the thought. Originality is to be commended and is fine if not carried too far. As a general rule, letters should have height and width but not thickness. Giving a third dimension to a letter calls attention to the letter itself and hinders the thought from being clearly given. There is flexibility about all letters and we can vary them by making them heavy or light, large or small but never distorted.

More size does not increase the legibility or the drawing power of a letter. A small letter well placed and not crowded will attract more attention and can be seen farther than a large letter crowded into a small space.

A short story contest has been announced by *Journal of the Outdoor*

Life, 50 W. 50th St., New York, N. Y. The Christmas Seal must enter the story, but need not dominate it. Details in the May, 1934, issue.

"Classes for Prospective Fathers," by E. V. Thiehoff, M.D. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Dec., 1933. "Something new for Cleveland in prenatal instruction."

Again *Syracuse Herald*, Syracuse, N. Y., has issued a tabloid magazine section devoted to "Our Babies," with numerous articles, signed and unsigned.

The Child Health Day tabloid supplement of *Honolulu Star-Bulletin* was matched by *Nippu Jiji*, a Japanese paper. Of the latter supplement says James G. Stone, Tuberculosis Assn. of Hawaii:

This is the first health supplement ever issued by a foreign language paper in Hawaii, and I am wondering whether it is the first foreign language child health supplement issued in the United States. At any rate, we will claim that it is until somebody disproves our contention.

An effective example of a brief for a special proposition has been prepared by the Committee on 8 Hours for Nurses, 132 East 45th St., New York, N. Y. A light green cover, with contents; 6 mimeographed pages of text; an off-set page reproducing "A Few Recent Headlines Reflecting Public Interest." A folder enclosure, and a leaflet of suggestions for workers are both well-written and attractively printed. Send 10 cents for samples.

MAGAZINE ARTICLES

Offered as source material; some deserve commendatory letters to editors.

"A Reporter at Large: The Surgeon," by Morris Markey. *New Yorker*, 25 W. 45th St., New York, N. Y. Feb. 3, 1934. 15 cents. Visit to a hospital operating room; convincing tribute to the care, skill and attitude of surgeons and nurses; an example of

high grade reporting; should be useful where there is unfounded criticism of a hospital.

"Back to the Midwife?" by H. H. Smith. *New Republic*, 421 W. 21st St., New York, N. Y. July 4, 1934. 15 cents. Questions as to the place of the midwife.

"Milk: Its Story from Farm to Town," by H. Ripperger. *New York Times Magazine*. June 10, 1934.

"My Daughter and I," by O. Rutter. *Rotarian*, Chicago, Ill. April, 1934. "A dad who wants his girl to grow up with eyes wide open."

"Mysteries and Medicals," by O. Ferguson. *New Republic*, 421 W. 21st St., New York, N. Y. July 4, 1934. 15 cents. Brief review of recent Hollywood output built around physicians.

"Paying for Health," by C. P. Streeter. *Farmer's Wife*, St. Paul, Minn. Sample free. How a Michigan county found that it could not afford to do without a county health unit.

"The Potato Defies the Dietician," by H. Ripperger. *New York Times Magazine*. May 13, 1934.

"Social Work in Hospitals," by H. M. Bartlett. *Junior League Magazine*, 305 Park Ave., New York, N. Y. June, 1934. 30 cents.

PUBLIC HEALTH BULLETINS

"Bulletins" or "house organs" issued by many health agencies represent a surprising range of interest or lack of interest in the readers.

Now may well be the time for all good editors to review the past year's out-put, seeking to determine what changes might be introduced next fall.

The following with an additional

paragraph is the Fourth of July message of the Middletown, N. Y., *Bulletin*:

When the fireworks begin to shoot, remember this story. General Leonard Wood recovered from a severe gunshot wound inflicted when a mortar shell burst inside a gun, exploding it. But his small grandson died from tetanus resulting from a wound produced by a toy pistol. It isn't the size of the firearm or of the injury which tells the story.

In "Facts and Health" Dr. Dowling gives 3 pages to an effective presentation of the values of a local health survey. *Birmingham's Health*, Jefferson Co. Board of Health. June, 1934.

"A Philosopher Looks at Health," quoting from Thomas Carlyle, is an example of usable material to be gleaned from the library. In *Weekly Bulletin*, California Department of Health, Sacramento. March 17, 1934.

Two pages of quotations from newspaper editorials appear in *State Board of Health Bulletin*, Madison, Wis. The editors say some of the things the State Board likes to tell its readers.

"What Is Your Answer?" is a page of questions in *Understanding the Child*, Massachusetts Society for Mental Hygiene, 3 Joy St., Boston, Mass. 15 cents. Numbers indicate pages where the answer may be found to confirm the reader's answers.

Michigan Out-of-Doors is now *Health*, issued monthly by Michigan Tuberculosis Assn., Lansing.

Monthly Bulletin, Indiana Division of Public Health, Indianapolis, has been revived under the editorship of Dr. Thurman B. Rice.

Bulletins are issued now by the Greater Vancouver Health League and the Provincial Sanatorium at Charlottetown.

BOOKS AND REPORTS

Japanese Medicine, Vol. XII of "*Clio Medica*" Series—By Y. Fujikawa, M.D. Translated from the German by John Ruhrah, M.D. New York: Hoeber, 1934. 114 pp. Price, \$1.50.

This belongs to the series of handbooks published under the general title "*Clio Medica*," edited by E. B. Krumbhaar, M.D.

The author divides the subject according to the ten political periods, beginning with the mythical period, which includes all Japanese history prior to 96 B.C., and ending with the present reign of the Meiji family who came on the Imperial throne in 1868. The book is another revelation of the fact that the Japanese are not originators but borrowers of great adaptability.

Medicine was probably first introduced into Japan from Korea which had long practised Chinese medicine. Deeply impressed, the Japanese sent students to study Chinese medicine at its source. For the first 1500 years of the present era Japanese practitioners depended largely upon the Chinese for their methods and inspiration. In the 6th century Buddhism was introduced into Japan from Korea and China and rapidly came into national favor. This tremendously stimulated Japanese interest in the Chinese medicine of that day because the Buddhist missionary priests from the mainland were generally physicians as well. In time Buddhist priests in Japan came to have an influence in their own country comparable to that of the Christian monks in Europe in the Middle Ages. In their treatment of disease they naturally laid more stress on prayer than on medicine. "When great epidemics appeared it was customary to appease the plague demons with prayers and incan-

tations. But smallpox patients were driven out of their homes and treated in isolation houses."

In a chronological table, the author frequently refers to national epidemics of various kinds. In 1512 A.D., he speaks of an epidemic skin eruption which came either from China or the Loochoo Islands, and which the author considers was the introduction of syphilis into Japan. He also refers to several febrile epidemics in the 18th century which he implies were influenza.

European medicine was introduced into Japan in 1556 by a Jesuit medical missionary from Portugal. For the next 300 years Western medicine was successively banned and reintroduced. Sometimes all was banned except surgery which was always accepted as superior to internal medicine from Europe. Following the Portuguese came Dutch, and soon after German physicians. As Western medicine came in the influence of Chinese medicine steadily waned, but again and again the latter would recrudescence, as Western medicine was for periods ostracized together with its handmaiden, Christianity.

Immediately after the opening of Japanese ports to foreign trade, following Admiral Perry's display of the American fleet in the port of Yedo in 1854, and the subsequent civil war which brought in the rule of the Meiji family in 1868, Western medicine, along with Western arts of war, was officially recognized. The government sent commissioners to Europe and America to study everything. One result was that the German language was officially adopted as the medium of instruction for most higher learning, including medicine. Japanese students were sent

to Germany, and many German physicians and scientists were brought to Japan to teach medicine and the premedical sciences.

The reviewer, who frequently visited Japan from 1910 to 1927, would hardly agree with the author of the last chapter, that the "Government has placed medical education on an equal footing with that of other countries." It is true that Japan has emerged from antiquated medicine and has adopted scientific medicine of the West in a remarkably short space of time, but her best medical schools and hospitals are not yet comparable to our best. The encouraging phase is that steady progress is being made and that her scientific men are more and more making important contributions.

The author states that Japan has 27 medical schools, of which 15 are classified as imperial in rank, more than 1,000 hospitals and over 50,000 physicians. Some 50 medical journals are published, the majority in the Japanese language, but several in German. This use of the German language rather than English has obviously tended "to make the English-speaking world overlook many meritorious works done in Japan."

HARVEY J. HOWARD

The Biology of Bacteria: An Introduction to General Microbiology—By Arthur T. Henrici, M.D. *New York: D. C. Heath and Company, 1934.* 482 pp. Price, \$3.60.

This book is the outcome of the successful teaching of various phases of bacteriology by the author over a number of years. It is a most interesting and accurate presentation of the subject in which various ramifications of the science are indicated. Without going into detail, controversial questions are suggested to the student and the known facts concerning these questions are presented. An attempt is made to

interest the student in the history of bacteriology by using a style similar to that of de Kruif in "Microbe Hunters."

An unusually clear discussion of optics, including the use of the dark field condenser, is given in one of the earlier chapters. Apparently a slip, such as is often found in first editions, has occurred on page 33 in the use of the terms "acid side" and "basic side" of the isoelectric point. This gives rise to an incorrect statement of the nature of the charge on an amphoteric substance.

The relationship of bacteria to other organisms is considered in sections dealing with protozoa, algae, fungi, and ultramicrobes. Technical methods are given in detail as need for their use arises rather than in a special section. A chapter dealing with heredity and variations of bacteria is very opportune in view of the literature which has recently accumulated on this subject. The truly scientific aspects of bacteriology are discussed in sufficient detail for the needs of the beginning student.

Sections on molds, protozoa and virus diseases complete the book. It contains a number of well selected, and for the most part, original, illustrations. The style and make-up of the text are excellent. The volume is unusually free from errors of any sort.

This is not just another textbook on general bacteriology, but a different one. It is suitable for students in general bacteriology regardless of the field of the science in which they may expect to specialize.

NEWELL R. ZIEGLER

Jimmy Chew—By Harrison W. Ferguson, D.D.S. *Chicago: Issued by Good Teeth Council for Children, 1934.* 31 pp. Paper.

This little booklet explains, under the four headings of "Right Food," "Chewing Exercise," "Tooth Brush,"

and "Your Dentist," the fundamentals of tooth development and care. It is intended for young children and should attract their interest by its simplicity and numerous illustrations.

Good Teeth Council is the latest addition to the group of organizations with an educational purpose and a commercial background. There is in "Jimmy Chew," however, only one casual reference to chewing gum with which only the most ardent sticklers for æsthetics could find any fault.

A foreword explains that the booklet has the approval of educators, health workers, nutritionists, and the dental profession. For free copies, communicate with Good Teeth Council for Children, 400 North Michigan Boulevard, Chicago.

JOHN HALL

Health Workbook for College Freshmen—By Kathleen Wilkinson Wooten. Published by the Author, Milledgeville, Ga. (2d ed.), 1934. 214 pp. Price, \$1.50.

This text or workbook is designed as "An Orientation course in personal, home, and community hygiene."

Its introduction discusses several important factors relating to the health education program such as the qualifications of the teacher, health supervision of college students, correlation of various college departments to secure better student health, suggestions to the teacher of freshman hygiene, and the integration of freshman health and physical education courses.

Each of the 47 chapters is an outline covering the content to be noted, activities to be used in study, prevention, or correction. Each chapter is concluded with a generous bibliography on the topic concerned. More specific references, *i.e.*, giving title of chapter, would save the student much time, and make his study more gratifying and profitable.

A general bibliography following the

group of lessons, together with a list of sources, organizations, and magazines from which material may be secured, gives added value.

This text is a radical departure from the usual college textbook of hygiene, and conforms more nearly to the modern concept of college teaching.

CHARLES H. KEENE

Studies on the Possible Intoxicating Action of 3.2 Per Cent Beer—By A. J. Carlson, N. Kleitman, et al. Chicago: University of Chicago Press, 1934. Price, \$.75.

These experiments, undertaken to study the possible intoxicating effects of 3.2 per cent beer on man, were in part financed by a grant from the U. S. Brewers Association to the University of Chicago.

Three measurements were made—(1) alcohol concentration in blood and urine; (2) objective performance tests; and (3) subjective judgments of change in behavior of the subjects by observers. Sixty-three pages are given to descriptions of the experimental work, with illustrations and tables. For the average reader the Discussion and Summary will be found the most useful part of the report.

It is well known that many definitions of drunkenness have been given from its social, legal, and physiological aspects. The report of the Alcohol Investigation Committee of the British Medical Research Council on this point is quoted and discussed, also the discussion of the Committee of the Judiciary, U. S. Senate.

The writers of this report point out that a number of things may bring about in certain people some of the changes which have been attributed to alcohol, and that certain people, without taking any alcohol, commit misdemeanors, indiscretions, and crimes which others are guilty of only when under the influence of liquor. They

believe that the concentration of alcohol in the blood seems to be one of the most reliable of the objective criteria of intoxication.

The Summary gives a résumé of the 7 types of experiment carried out, in which some 113 subjects participated, beer being given to some in very moderate amounts and at well spaced intervals, while for others there was forced drinking every 30 minutes for 8 consecutive hours.

The conclusion is based on the Senate Committee's definition of an intoxicating beverage, and the writers decide that "beer containing 3.2 per cent alcohol by weight is not an intoxicating beverage."

The report is lucidly written and the auspices under which the work was done assure one of its authenticity.

MAZÛCK P. RAVENEL

Maternal Mortality and Morbidity

—By J. M. Munro Kerr, M.D., F.R.F.P.S. (Glas.), F.C.O.G. Baltimore: Wood, 1933. 382 pp. Price, \$8.25. (Made and printed in Great Britain.)

This is the most complete and exhaustive study of maternal mortality and morbidity that has come to my attention. While the material is drawn largely from England, Scotland, and Wales, the basic factors are comparable with those found in the United States. At the end of an illuminating introduction, Dr. Kerr states:

... it emerges from the inquiries which the following pages summarize that puerperal mortality and morbidity in this country can be reduced by a figure which, on a conservative computation, may be stated at not less than 40 per cent, but only if the essentials already stated are complied with.

A satisfactory maternity service for the country can be created without disturbing existing conditions to any great extent: no one engaged in obstetric practice need have his position prejudiced.

The volume is divided into 5 main

parts, the first setting forth in detail all of the causes, direct and indirect, which affect puerperal mortality. A chapter on maternal morbidity and subsequent disablement by Dr. Donald McIntyre and one on neonatal death and disablement by Prof. Geoffrey B. Fleming are especially informative.

Part II deals entirely with prevention, both in its antenatal aspects and in the suitable management of labor. These two chapters form the core of the book and are replete with practical suggestions for the prenatal care of both healthy women and women with inter-current diseases. Conservative aseptic obstetrics is urged. Radiography is recommended as a method of examinations which may be of the greatest value in diagnosis of obscure conditions during pregnancy. Six interesting radiographs are given to illustrate this section.

Part III takes up in 7 chapters the various services available, such as domiciliary service, hospitals, prenatal clinics, midwifery service, and transport service. A whole chapter is devoted to the education of medical students in obstetrics and gynecology.

In Part IV, Dr. Kerr presents his scheme of organization for a national maternity service. "This scheme presumes the establishment of a national maternity service based on the insurance principle." It is recommended that there be a Central Directing Board associated with the Ministry of Health for England and Wales and the Department of Health for Scotland. While this service is designed primarily for the artisan class, largely of insured persons, and for the poor and destitute, its provisions are so broad that it will affect the whole obstetric practice. This scheme is compared with three others which have been under consideration recently.

The whole volume will bear careful study in view of recent investigations

of a similar nature in the United States and elsewhere. The book is well presented and conveniently arranged for reference.

RICHARD A. BOLT

Modern Sewage Treatment—By T. P. Francis. London: *The Contractor's Record, Ltd.*, 1932. 322 pp. Price, \$7.50.

This is a broad but somewhat brief outline of sewage treatment developed by the author in a most attractive and instructive manner. The fundamentals in the treatment of any sewage are emphasized and the book developed around these fundamentals. I believe it is one of the best introductions to the problems of sewage treatment I have ever read and for that reason would recommend it highly for students or for sanitary engineers who are broadly interested but perhaps not actually

operating or engaged in the designing of plants.

To those who are more intimately connected with the operation or design of plants, and especially to young engineers, it would be valuable as a reference book for the fundamentals, if supplemented by other books or current literature which would go further into the details of the specific problems concerned.

An appendix of 68 pages covers outlines of: (1) Sewage chemistry, (2) Hydrogen Ion concentration, (3) Theory of colloids, (4) Application of colloidal phenomena, (5) An outline of biology.

The book has many excellent sketches, drawings and pictures, in fact, about half of the book is composed of illustrations.

ALFRED H. FLETCHER

BOOKS RECEIVED

MEDICINE: A VOYAGE OF DISCOVERY. By Joseph Lobel. New York: Farrar & Rinehart, 1934. 334 pp. Price, \$3.00.

THE SCIENCE OF WORK. By Morris S. Viteles. New York: Norton, 1934. 442 pp. Price, \$4.00.

THAT HEART OF YOURS. By S. Calvin Smith. Philadelphia: Lippincott, 1934. 212 pp. Price, \$2.00.

CHILDREN OF THE NEW DAY. By Katherine Glover and Evelyn Dewey. New York: Appleton-Century, 1934. 332 pp. Price, \$2.25.

HYGIENE AND HOME NURSING. By Louisa C. Lippitt. Yonkers: World Book Co., 1934. 424 pp. Price, \$1.24.

WORK RELIEF IN GERMANY. By Herta Kraus. New York: Russell Sage, 1934. 93 pp. Price, \$0.50.

INFLUENZA. Part II. By David Thomson and Robert Thomson. London: Bailliere, Tindall & Cox, 1934. 1557 pp. Price, \$15.50.

MILITARY MEDICAL MANUAL. By the Military Surgeon. Washington: National Service Publishing Co., 1934. 774 pp. Price, \$4.50.

THE ANCESTRY OF THE LONG-LIVED. By Raymond Pearl and Ruth DeWitt Pearl. Baltimore: Johns Hopkins Press, 1934. 168 pp. Price, \$3.00.

KEEPING CAMPERS FIT. By Elena E. Williams. New York: Dutton, 1934. 227 pp. Price, \$2.50.

THE PNEUMONOKONIOSES (SILICOSIS) BIBLIOGRAPHY AND LAWS. By George G. Davis, Ella M. Salmonsens and Joseph L. Earlywine. Chicago: Industrial Medicine, 1934. 482 pp. Price, \$7.50.

DEATH RATES BY OCCUPATION. Edited by Jessamine S. Whitney. New York: National Tuberculosis Assn. 32 pp. Price, \$1.00.

LEISURE-TIME INTERESTS AND ACTIVITIES OF BUSINESS GIRLS. A Research Study. By Janet Fowler Nelson. New York: Womens Press, 1934. 113 pp. Price, \$0.75.

MANUAL OF NURSERY SCHOOL PRACTICE. By Iowa Child Welfare Research Station. Iowa City: University of Iowa, 1934. 215 pp. Price, \$1.00.

THE DANGEROUS AGE IN MEN. By Chester Tilton Stone. New York: Macmillan, 1934. 105 pp. Price, \$1.75.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

The Little Fleas That Bite 'em— Phage plays a part in modifying the sensitivity of invading organisms to the destructive action of complement in each instance of invasion in which the diseased host produces antibodies. The experiments reported complete the fifteen-year-old study of the general behavior of phage.

D'HERELLE, F., and RAKIETEN, T. L. Mutations as Governing Bacterial Characters and Serologic Reactions. *J. Infect. Dis.* 54, 3:313 (May-June), 1934.

Testing Vitamin D Milk—A method is proposed for testing the potency of milk fortified with antirachitic vitamin. The importance of clinical experience to supplement laboratory studies is emphasized in a second paper reporting upon research along the lines of the proposal.

ELIOT, M. M., *et al.* Potency of Milks Fortified with Respect to Antirachitic Properties (and) Prevention of Rickets by Milk Fortified with Vitamin D from Cod Liver Oil. *J.A.M.A.* 102, 22:1323 (June 2), 1934.

Detecting Food Impurities—Some of the problems of the British analyst of foods and drugs are recounted in an interesting dissertation given over largely to milk, but including jam, that most important part of the British dietary.

EVANS, J. Recent Advances in Food Analysis. *J. Roy. San. Inst.* 54, 12:599 (June), 1934.

Infantile Paralysis Outbreak Studied—Convalescent serum is believed by the author to have been of value in the treatment of poliomyelitis cases in a Quebec epidemic occurring in 1932. Evidence of increased resistance due to nonspecific immunity support the

earlier suggestions in regard to this phenomenon. Other findings of the study are recorded.

FOLEY, A. R. The 1932 Epidemic of Poliomyelitis in Quebec. *Canad. Pub. H. J.* 25, 6:260 (June), 1934.

Dangers to Granite Workers—Quarry drillers may be as dangerously exposed to granite dusts, and experience as high a tuberculosis death rate as do other pneumatic tool workers in cutting sheds. The dustiness in both occupations may be eliminated.

BLOOMFIELD, J. J., and DREESSEN, W. C. Silicosis Among Granite Quarriers. *Pub. Health Rep.* 49, 23:679 (June 8), 1934.

International Coöperation in Public Health—The broad subject indicated in the title is interestingly presented in a series of lectures which together should prove to be an invaluable historical document.

BUCHANAN, G. S. International Coöperation in Public Health. *Lancet*, 1, 17:879 (Apr. 23), 1934.

When to Revaccinate—Immunity conferred by a single vaccination usually lasts longer than the traditional 7 years. The protection lasts for 20 years in most individuals.

DEARING, W. P., and ROSENAU, M. J. Duration of Immunity following Vaccination against Smallpox. *J.A.M.A.* 102, 24:1993 (June 16), 1934.

Preventorium?—Do preventoriums really prevent tuberculosis? A study of the results in 705 children cared for at a Boston preventorium shows that over a 10-year period only one child has died of tuberculosis and two cases developed. What would have happened had there been no care given, we can-

not know, but the surveyors of the project are convinced that it has been well worth while.

HAWES, J. B., *et al.* A Study of Ten Years' Work at the Prendergast Preventorium of the Boston Tuberculosis Association. *New Eng. J. Med.* 210, 25:1321 (June 21), 1934.

Cows, Not Pigs, the Offenders—Bovine type organisms of the abortus-meletensis group were responsible for the cases of undulant fever occurring in New York State. Most patients had no contact with cattle but drank raw milk.

GILBERT, R., and COLEMAN, M. B. Undulant Fever in New York State. *J. Infect. Dis.* 54, 3:305 (May-June), 1934.

When Eyes Need Help—All the information one would need about the incidence of eye refractions is available in this survey of 8,758 representative white families. Headache was the most frequent cause. A dozen other useful findings are recorded.

COLLINS, S. D. Frequency of Eye Refractions in 9,000 Families Based on Nationwide Periodic Canvasses 1928-1931. *Pub. Health Rep.* 49, 22:649 (June 1), 1934.

Social Responsibility in the New Order of Things—Can we accomplish social planning under democratic leadership or shall it be forced upon us by a dictatorship? There is no other choice but chaos. Upon this postulate the author considers nursing, and finds that the nurse promises to meet the

challenge of the new order. In some similar way to public health nursing, medical care must be provided. Health services must be expanded to meet the new concepts of social responsibility. Don't miss this dissertation.

WINSLOW, C.-E. A. The Challenge of Today. *Pub. Health Nurs.* 26, 6:283 (June), 1934.

Toxoid for Adults—Experience with medical students and nurses leads the authors to conclude that toxoid is a satisfactory immunizing agent for adults provided the described precautions are observed.

KELLER, A. E. and HARRIS, S. The Use of Diphtheria Toxoid in Immunization of Medical Students and Nurses. *J.A.M.A.* 102, 26: 2163 (June 30), 1934.

They Shall Not Die—Maternal mortality can be improved if we have the will to put preventive measures into effect. What these measures are is outlined in convincing detail.

KOSMAK, G. W. Community Responsibilities for Safeguarding Motherhood. *Pub. Health Nurs.* 26, 6:292 (June), 1934.

For Stylish Stouts—Milk and bananas are proposed as a basis for a satisfactory reducing diet, on the grounds of simplicity, low cost, ready availability, palatability, high satiety value, low salt content and demonstrated effectiveness.

HARROP, G. A. A Milk and Banana Diet for the Treatment of Obesity. *J.A.M.A.* 102, 24:2093 (June 16), 1934.

ASSOCIATION NEWS

THE HUNTINGTON LIBRARY AND ART GALLERY, PASADENA, CALIF.

THE HUNTINGTON LIBRARY AND ART GALLERY

WITHIN a period of 20 years Henry Edwards Huntington, a retired capitalist who had amassed a fortune in developing transportation systems, assembled an outstanding group of 18th century English paintings and a library of source material for the study of English and American culture that ranks with the best collections of its type in this country and in England. The panoramic view reproduced on this page gives an idea of the visitor's first impression—two stately buildings in a beautiful setting on the crest of a knoll on a 207 acre estate, which includes a 10 acre cactus garden, the Japanese garden, the rose garden, and collections of palms and cycads. The rarity of the plants draws many students of botany, including organized groups devoted to garden study and landscaping.

The deeds of trust created a self-perpetuating board of 5 trustees with the responsibility of administering the trust as a "free public research library, art gallery, museum, and botanical garden," whose object is the "advancement of learning, the arts and sciences,

and to promote public welfare." An increasing number of scholars from English and American universities make use of the Huntington Library for its unique and rare material.

In the new wing of the Art Gallery one may see such famous masterpieces as *The Blue Boy* of Gainsborough, the portrait of Mrs. Siddons, the great English actress, *The Tragic Muse*, by Reynolds, and little Miss Sarah Moulton-Barrett, "*Pinkie*," by Lawrence.

Through the courtesy of the Huntington Library a special exhibit on Public Health in Tudor England will be shown to visitors at the Annual Meeting in Pasadena. This is scheduled for Tuesday afternoon, September 4. Rarely do public health workers have the opportunity to see on display the proclamations which were the origin of the development of our public health principles. The following article written by Sanford V. Larkey, M.D., will refer to some of the many items of interest which those engaged in public health work will find at the Huntington Library.

PUBLIC HEALTH IN TUDOR ENGLAND

SANFORD V. LARKEY, M.D.

*Assistant Professor of Medical History, University of California
Huntington Library International Research Fellow*

TO THOSE interested in the history of public health measures, 16th century England is particularly important, for during this century and in the early part of the 17th century, there developed those ideas of the state's direct concern with the health of its citizens which are the basis of our modern public health organization.

For an appreciation of the problem as it presented itself to the medical men of those days it is necessary to have some understanding of the knowledge of the time. It is the purpose of the exhibition of books and manuscripts at the Huntington Library to give this background, to indicate the part played by the government, and the origin of certain public health measures. In addition to the exhibition, "Medical Knowledge in Tudor England," there will also be shown various books and documents illustrating the actual practice of public health administration in Elizabeth's reign, and the extension of this in the time of James I. Included in this material will be proclamations—for control of the epidemics of plague, for improving housing conditions, pure food regulations, bills of mortality, hospital rules, and the official London Pharmacopoeia.

Naturally, the practice of medicine and the measures to combat disease were based on the theories then prevalent. These traditional beliefs are illustrated by a number of works on the subject, and from these one can get a good idea of what the Elizabethan doctor thought and how he practised his art. Great emphasis was put on the preventive

aspects of medicine. Thomas Cogan, writing in 1584, says:

The art of Phisicke . . . hath two principall partes: the one declaring the order howe health may be preserved, the other setting foorth the meanes how sicknes may be remedied. Of these two partes (in mine opinion) that is more excellent which preserveth health and preventeth sicknes.

The best doctors of the time appreciated their duty to the public. True followers of Hippocrates, they had high ethical standards and deplored the activities of quacks and charlatans. There were many pleas for licensing requirements and for stricter laws. In 1518, on the advice of Thomas Linacre, the College of Physicians was founded, to control medical practice in London. It is significant that from this year also date some of the most important public health measures, initiated by the Privy Council, as the isolation and marking of infected houses, the isolation of goods from infected houses, the first London plague orders, and the first mention of bills of mortality.

This very important factor in controlling disease, the publication of bills of mortality, listing the numbers dead in each parish of the city, and the diseases of which they died, was inaugurated in England, and an example of one of these very rare documents will be exhibited.

The plague orders were expanded into a book for the use of the entire country, about 1588. In this, Elizabeth enunciated the policy of the participation of the state in matters of health.

This was consistent with her general attitude, that the welfare of all the people was the concern of the state, and that the state existed for the people. Thus, it could interfere with individual liberty, if the good of all the people were at stake. There were the usual protests that such rules infringed on personal rights. Some people insisted, on religious grounds, that the plague was not infectious, and that one should not attempt to avoid it, as this showed a lack of faith in God. This attitude often interfered with certain sections of the "Orders" concerning assemblies of people in time of plague. The idea that the plague was caused by the wrath of God frightened the people in the more serious epidemics, and there was a section in the "Orders" forbidding ecclesiastical or lay persons "to utter such dangerous opinions upon the payne of imprisonment." A number of preachers were thrown into jail for continuing to spread such doctrines.

In these "Orders" and in similar works, the procedure for dealing with an epidemic was outlined. Important factors in this were the isolation of the infected, rules against assemblies of people, closing of schools, cleaning of the streets, provision for food supply, burial of the dead, and the treatment of the sick. It had been suggested that the city hire physicians and surgeons to care for those with plague, and in the "Directions," set down by the College

of Physicians in 1636, this scheme was adopted. These men were paid a stipend by the city "to apply themselves to the cure of the Infected." If they died in service their widows were given a pension for life.

The organization thus outlined undoubtedly did much to check the spread of the plague but, since the real cause of the disease and the means of transmission were not known, it was impossible to eradicate it. There were some devastating epidemics. In 1603 and in 1625 the death rate in each instance was over one-sixth of the total population. At these times the people became panic-stricken and the system broke down. The rules could not be enforced, the dead were left unburied, and everyone looked out for himself as best he could. Many of the doctors gave up in despair and fled from the cities but some courageously stayed and cared for the afflicted. Those hired by the city were bound by oath to remain. This human factor is one of the most difficult elements in administering any general scheme, as we realize today.

But the method of public health supervision described in the manuscripts and rare printed tracts in the Huntington Library exhibition was fundamentally sound and is the basis of our modern system, which now, with increased scientific knowledge of disease, has almost freed the world from such epidemics.

RAILROAD TRAVEL TO PASADENA

THE attention of the membership is again called to the fact that no identification certificates or special credentials are necessary this year to secure reduced railroad rates to Pasadena. Summer excursion fares are effective from most points, or short-term special rates. Consult your local ticket agent

concerning your transportation if you are not traveling on the A.P.H.A. Special Train. The Association will make all arrangements for the group on the Special.

See page 670 of the June *Journal* for 45-day, round trip summer tourist fares from various centers.

THE PASADENA ANNUAL MEETING

GENERAL INFORMATION

PREVIOUS issues of the *Journal* have carried information to which members may wish to refer if they are making plans now to attend the Pasadena sessions. The following may be helpful:

June, pages 668 and 669. Pasadena hotels, with rates. Reservation blank

June, page 670. Forty-five day round trip, summer tourist rates from principal points.

July, pages 778 to 806. Scientific program, Health Education Institute program, meetings of other organizations, places of general and scientific interest in Pasadena and in California.

A.P.H.A. SPECIAL TRAIN AND ALL-EXPENSE TOUR

A MOST representative group of Association members, their families, and their friends have reserved accommodations or signified their intention of doing so on the Special Train to Pasadena which the Association is sponsoring. The all-expense, conducted tour includes an evening in Chicago at the World's Fair, attendance at the Indian Ceremonials at Gallup, N. M., a day at the Grand Canyon, a day and an evening in San Francisco, a day in Stockton, Lodi and Sacramento, several hours in Salt Lake City and Denver, with entertainment and sightseeing at each stop. Detailed information about the tour was sent to the membership in June and will be repeated on request.

If you ride the A.P.H.A. Special, you will find in the delegation many of your old friends, and you will make many

new ones. If you cannot make the complete tour, join it for such portion of it as you find convenient.

You must let us know in advance, if we are to have the pleasure of your company for all or for any part of the journey. We are sorry, but it will not be possible for you to join the Special Train en route unless arrangements with this office have been concluded before the departure of the train from New York on Tuesday, August 28.

SPECIAL SESSION ON POLIOMYELITIS
SINCE the July *Journal*, containing the preliminary program, went to press, the Health Officers Section has arranged a symposium on poliomyelitis, announced here for the first time. The program follows:

SYMPOSIUM ON POLIOMYELITIS

- Previous History of Poliomyelitis in California. J. D. DUNSHEE, M.D., and IDA MAY STEVENS.
- Administrative Problems. J. L. POMEROY, M.D., and GEORGE H. ROTH, M.D.
- Clinical Features This Year. A. G. BOWER, GEORGE M. STEVENS, M.D., R. W. MEALS, MARY BIGLER, JOHN EWING, and VERNON HAUSER.
- Poliomyelitis in Northern California. KARL F. MEYER, M.D.
- Pathology. ROY VAN WART, CYRIL COURVILLE, and E. M. HALL.
- Experimental Investigations. LESLIE WEBSTER, JAMES TRASK, and JOHN PAUL.
- Epidemiology. JAMES P. LEAKE, M.D., HOWARD CHOPE, E. O. CEDAR, W. PALMER DEARING, M.D., and A. G. GILLIAM.
- Serum in Prophylaxis and Treatment Including Hospital Outbreak. JOHN F. KESSELL, Ph.D.
- Orthopedic Phases. JAMES V. LUCK.
- Discussion opened by: GEORGE PARRISH, M.D., and C. L. LOWMAN.

A WORD TO THE THRIFTY

VERY few of us, at any time, will entirely disregard an opportunity to reap a financial benefit from thrifty buying or from careful and calculated investments. Why, then, do A.P.H.A. Fellows continue to overlook the gain inherent in Life Membership? They should do so no longer.

A careful study of the chart on the opposite page will reveal the savings which will accrue to Fellows by taking Life Membership at various ages. For example, a Fellow applying for Life Membership at the age of 40 will save a little over \$75. This saving (three-quarters of the cost of Life Membership) is of such proportion as to warrant careful investigation.

Beside the straight economical benefits, others accrue to Life Members: (1) annual payment of bills is onerous to some—Life Membership eliminates that; (2) in times of low income, a Life Member is assured of his continuation in the Association, thereby safeguard-

ing for all time his professional standing; (3) a Life Member can pride himself on the high type of professional spirit he has shown by investing in the future of public health work.

Life Membership dues need not be paid at once—the payments may be spread over a year from the date of election, which takes place at each Annual Meeting.

Some may ask—What is done with the dues of Life Members? They are set up in a Life Membership Fund entirely separate from other Association funds, and only the interest therefrom is used to carry the cost of each Life Member's participation in Association activities.

It must be obvious that the advantages of Life Membership far outweigh the disadvantages. The Committee on Fellowship and Membership, therefore, urges each and every Fellow to give serious thought to the desirability of applying for Life Membership.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers

- Edmundo Avina, M.D., Avenida Alcalde No. 134, Guadalajara, Jal., Mex. Chief of Coördinated Services (Federal and State)
 Edward J. Farrell, M.D., 3206 Oak Park Ave., Berwyn, Ill., Health Director, City Health Dept.
 H. F. Hutchinson, M.D., Pearl St., Forestville, N. Y., Health Officer
 Robert D. Hyde, M.D., 9615 Brighton Way, Beverly Hills, Calif., Acting Health Officer, District of Los Angeles County
 W. Lassiter, M.D., Gainesville, Fla., City Health Officer
 Charles Nelson Leach, M.D., C.P.H., Volksgesundheitsamt, Hanuschgasse 3, Vienne I, Austria, Field Director, International Health Division, Rockefeller Foundation (Assoc.)
 Gustavo A. Rovirosa, M.D., Unidad Sanitaria Cooperativa, Orizaba, Vera Cruz, Mex., Director of Coöperative Health Unit of Orizaba

Laboratory

- George Dexter Brigham, Ph.D., State Board of Health, Montgomery, Ala., Charge of Laboratory
 Clara Winifred Burnham, A.B., 2451 Hearst Ave., Berkeley, Calif. (Assoc.)
 Julia M. Coffey, A.B., 373 State St., Albany, N. Y., Assistant Bacteriologist, Division of Laboratories and Research, State Department of Health
 Roy Edward Coupal, P. O. Box 606, Eureka, Calif., City Bacteriologist
 Jesse H. Inman, M.D., Kern General Hospital, Bakersfield, Calif., Director, Public Health Laboratory
 Carl E. Wallace, B.S., 718 Medical Arts Bldg., Tacoma, Washington, City Bacteriologist

Public Health Education

- Anne Simpson Aller, M.A., 2508 Benvenue Ave., Berkeley, Calif. (Assoc.)
 Lu Crandall, A.B., 1801½ Azard St., Auburn, Calif., Supervisor of Health, Placer County Schools
 Avis C. Eaton, M.D., 135 Stockton, San Francisco, Calif., Venereal Disease Clinics
 Russell Wilbur Force, D.D.S., 605 First Trust Bldg., Pasadena, Calif., Chairman, Clinic Committee, Pasadena Dental Association

- Honorah Hughes, 6115 Arcade Bldg., Seattle Wash., Executive Secretary of the Anti-Tuberculosis League of King County
 Elizabeth McFadden, A.B., 340 South 16th St., San Jose, Calif., Head, Health & Hygiene Dept., San Jose State Teachers College
 Henrietta Morris, Sc.D., 117 N. W. Trinity Place, Portland, Ore., Health Education Director, Oregon Tuberculosis Association
 Joseph Shilen, M.D., Leech Farm, Pittsburgh, Pa., Supt., Tuberculosis Sanitarium
 David B. Treat, A.B., 909 Berkeley Road, Phoenix, Ariz., Coördinator, Health Service, Phoenix Union High School
 Beatrice H. Woodward, R.N., 582 Market St., Room 802, San Francisco, Calif., Field Director, California Tuberculosis Association

Vital Statistics

- Francis C. Driscoll, A.B., Quincy Health Department, Quincy, Mass., Statistician

Public Health Engineering

- Claude H. Ballard, Blountville, Tenn., Sanitary Inspector
 Francis Wilson Kittrell, M.S., State Dept. of Public Health, Nashville, Tenn., Associate Sanitary Engineer

Child Hygiene

- Florence B. Jordan, State Board of Health, Helena, Mont., Assistant Director, Child Welfare Division

Public Health Nursing

- Edith B. Aldridge, R.N., Room 203, District Bldg., Washington, D. C., Supervisory Nurse, Child Hygiene Service, Health Department
 Myrtle C. Applegate, 554 S. Third St., Louisville, Ky., Supervisor, Public Health Nursing Assn.
 Helen Aydelott, R.N., 1230 Villa Place, Nashville, Tenn., Staff Nurse
 Alice Frances Boyer, Bureau of Child Hygiene, Room 304, State Department of Health, Trenton, N. J., Supervisor of Nurses
 Mary Brain, 275 Hubbard Ave., Salt Lake City, Utah, Metropolitan Nursing Service
 Agnes Brown, R.N., 1847 S. 6th East, Salt

- Lake City, Utah, Nurse, Metropolitan Life Ins. Co.
- Florence B. Bussell, R.N., 1025 2nd Ave., Oakland, Calif., Supervisor of Nurses
- Rose K. Butler, R.N., 328 Maple St., Holyoke, Mass., Executive Director, Holyoke Visiting Nurse Association
- Loneta M. Campbell, 3001 Woodburn Ave., Cincinnati, O., Director, Visiting Nurse Association
- Frances E. Curtis, 122 North H St., Madera, Calif., County Health Nurse
- Margaret Douglas, R.N., Monteagle, Tenn., County Nurse, Grundy County
- Winifred L. Fitzpatrick, R.N., 100 North Main St., Providence, R. I., Director, District Nursing Association
- Alma E. Hartz, 403 City Hall, Cedar Rapids, Iowa, Director of Nursing
- Martha I. Hauk, A.B., Hackley School Bldg., Muskegon, Mich., Supervising School Nurse
- Bertha B. Holmes, Community House, Purchase, N. Y., Public Health and Community Nurse
- Margery Keeler, 28 Strawberry Hill Ave., Stamford, Conn., On Board of Stamford Visiting Nurse Association
- Linnie M. Laird, 2315 N.E. 43d Ave., Portland, Ore., School Nurse
- Pauline Marshall, R.N., 303 E. St., Salt Lake City, Utah, Metropolitan Nurse
- Martha McEntire, 67 Fontenelle Apts., Ogden, Utah, Metropolitan Life Insurance Co., Nurse
- Ada Cecelia McGrath, R.N., 174 N. Walnut St., East Orange, N. J., Supervisor of School Nurses
- Burtice A. Rees, 65 Court St., Buffalo, N. Y., State Supervisory Nurse
- Valeria Rittenhouse, R.N., University of Wyoming, Laramie, Wyo., University Nurse
- Cornelia Roys, R.N., 402 West Main St., Lebanon, Tenn., Public Health Nurse, Wilson County
- Hilda Marie Schneider, Community Hospital, San Mateo County, San Mateo, Calif., Supervising Nurse
- Mary B. Scott, M.A., 14 Bank St., Fall River, Mass., Supt., District Nursing Association
- Josephine L. Shefner, R.N., Haskell Institute Hospital, Lawrence, Kansas, U. S. Indian Service
- Mary Elizabeth Stearns, R.N., 194 Concord St., Manchester, N. H., Supervisor of District Nursing Association
- Elizabeth S. Taylor, R.N., Bureau of Public Health Nursing, State Department of Health, Hartford, Conn., Director
- Justine L. B. Thorp, R.N., 318 W. Cedar St., Compton, Calif., School Nurse, Public Health Nurse
- Cornelia van Kooy, R.N., State Board of Health, Capitol, Madison, Wis., Director, Bureau of Public Health Nursing
- Dorothy A. Whitelock, 1040 Salem St., Chico, Calif., City Public Health Nurse

Epidemiology

- A. M. Menzies, M.D., D.P.H., Provincial Board of Health, Victoria, B. C., Canada, Epidemiologist
- Richard M. Taylor, M.D., Institut Bouisson-Bertrand, Rue Ecole de Medecine, Montpellier (Herault) France, Field Director, International Health Division, Rockefeller Foundation (Assoc.)

Unaffiliated

- William Andre Elfer, St. Rose, La., Member St. Charles Parish Board of Health
- George U. Wood, Peralta Hospital, 434 30th St., Oakland, Calif., Superintendent

NEWS FROM THE FIELD

U.S.P.H.S. ENGINEERS TRANSFERRED

INFORMATION has been received that Sanitary Engineer Arthur P. Miller, F.A.P.H.A., of the U. S. Public Health Service, has been transferred from Norfolk, Va., to New York, to take charge of that Service of Sanitary District No. 1. He is located in the Sub-Treasury Building, New York.

At the same time Sanitary Engineer L. M. Fisher, F.A.P.H.A., was transferred to Washington, D. C., to assume charge of Sanitary District No. 2, which was moved back to Washington, D. C., from Norfolk, Va.

LEAGUE OF MENTAL HYGIENE IN BRAZIL

THE National League of Mental Hygiene of Brazil, according to its recent report, has been giving most of its attention in the 10 years of its existence to a campaign against alcoholism, to physical examinations of persons intending to marry, particularly men, and to child guidance work. The child guidance clinic established by the league is working with mentally retarded or otherwise mentally abnormal children in some of the public schools of Rio de Janeiro. Each child is given a thorough physical and psychological examination, and a written report of his condition with the necessary advice is presented to the parents. The results of this work are highly praised in Brazil.—*Archivos Brasileiros de Hygiene Mental*, Rio de Janeiro, 1933, vol. 6, No. 4.

TUBERCULOSIS CONFERENCE IN POLAND

THE Ninth Conference of the International Union Against Tuberculosis will be held in Warsaw, Poland, September 4-6. A special party is

being arranged to go from the United States, with a trip to Russia for those who can leave in advance. For information, write to the National Tuberculosis Assn., 50 West 50th Street, New York.

GERMAN HEALTH AND SAFETY MEASURES

THE rooms in which home work is done must be free from danger to the life, health, or morals of the workers. The Federal Minister of Labor may order for certain branches of industry or certain kinds of establishments measures for the protection of the workers' health, and also of public health; may entirely prohibit any home work that is combined with considerable danger to life, property, morals, or public health.

As under the old law, the employment of children of school age may be forbidden by the Minister of Labor, or the age limit may be raised.—*Reichsgesetzblatt*, Berlin, 1934, part I, p. 214; text of the home work law of 1923.

ITALIAN LAW REGULATING EMPLOYMENT OF WOMEN AND CHILDREN

EXTENT of Application of the Law—The Italian law of April 26, 1934, regulating the employment of women under 21 and of children under 15, supersedes the law of 1907 and its amendments. The new law is much more extensive in its application than the old; it applies to workers in a large number of occupations, including commercial ones, and to clerical as well as manual workers, whereas the old law applied only to manual workers in certain industries. The new law does not apply to domestic servants, home work-

ers, agricultural workers, maritime workers, employees of the National Government, of the provinces, nor of the communes.

BELGIUM—LAW REGULATING HOME WORK

INDUSTRIAL home work is regulated in Belgium, apparently for the first time, by a law passed February 10, 1934, which provides for the establishment of a national commission on industrial home work—the wages paid and the hygienic conditions under which such work is done. The commission is to include 3 employers and 3 workers, as well as a chairman not belonging to either class, who must be well versed in economic and social subjects. All the members are to be appointed by the King for 6 years. To aid in deciding on wages the commission may add temporarily to its membership 2 employers and 2 workers.

The commission is to have authority to make investigations with regard to wages and working conditions of home workers. At the request of workers or employers, it is to intercede in wage disputes and to recommend a minimum wage rate if the representatives of the workers and the employers fail to agree or if the wage rate that they agree upon is in its opinion too low. Payment of the wages recommended by the commission may be made compulsory by royal decree.

TYPHOID VACCINATION IN ILLINOIS

THE Illinois State Health Department has instituted a vaccination campaign against typhoid in 11 counties in southern Illinois. The work is being carried out in Jefferson and Fayette Counties and was scheduled to begin early in June in Saline, Williamson, Jackson, Union, Randolph and Madison Counties. It will be extended into remaining counties as soon as facilities permit.

NEW HEALTH UNIT IN MICHIGAN

THE establishment of the Van Buren County Health Department has been made possible by the W. K. Kellogg Foundation. Operation on a full-time basis was planned for July 1. The Foundation will supply most of the funds, it is stated, the state the usual annual subsidy of \$3,000 and the county office space and equipment.

HYGIENE AND SAFETY IN WORKSHOPS IN ITALY

THE workshops must be kept clean and well ventilated and must satisfy certain requirements of hygiene and safety; rules against overcrowding are prescribed. The factory-inspection office may forbid women and children to remain in the workshops during the rest periods.

Women under 21 and children under 15 may not be employed without obtaining an "employment book," in which is written a certificate of fitness, issued by a physician in the public service. In certain kinds of work, to be specified in a later decree, the employer will be required to provide physical examinations for women under 21 and children under 15 at regular intervals in order to ascertain whether they are able to continue the work; in certain dangerous, difficult, or unhealthful occupations such examinations may be prescribed for women of all ages and boys under 18.

In addition to providing for an increase in the number of workers subject to physical examinations, the law also provides for an increase in the number of examining physicians; besides the district health officers who made the examinations under the old law, physicians employed by public social welfare agencies, especially the National Bureau for Maternity and Infancy, will also be called upon to make such examinations.

Penalties are provided for violations

of the law, which will become effective at a date to be announced later.—*Gazzetta Ufficiale del Regno d'Italia*, Rome, No. 99 (Straordinario), 1934; translator's comment.

BIOGRAPHY OF DR. WELCH

THE trustees of Johns Hopkins University and its medical faculty have selected Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, to write the biography of the late Dr. William H. Welch.

ARIZONA PUBLIC HEALTH MEETING

THE Seventh Annual Meeting of the Arizona Public Health Association was held at Prescott, Ariz., June 5-6. A number of important papers were presented.

INTERNATIONAL LEAGUE AGAINST CANCER

AN International League for the Combat of Cancer was founded in Paris, March 24, 1934, at a meeting attended by representatives of 32 nations, it is reported. It is planned to have a permanent office in Paris and to publish a yearly report. The League also plans to organize an international convention in Rome, probably for 1936, to seek international cooperation in the field of statistics and in the campaign against quackery and in exchange of literature.

ANNUAL SCIENCE EXHIBITION

UNDER the auspices of the American Association for the Advancement of Science and Associated Societies, of Washington, D. C., there will be held an Annual Science Exhibition at Pittsburgh, Pa., December 27-30, 1934.

Special attractions announced are: exhibits and demonstrations in zoölogy, cosmic rays, deuterium, neutrons, induced radioactivity, stratosphere ex-

hibition, and talking films in the physical sciences from the University of Chicago, etc.

MEETING OF MILITARY SURGEONS

THE annual meeting of the Association of Military Surgeons of the United States will be held at the Medical Field Service School, Carlisle Barracks, Pa., October 8, 9, and 10, 1934. No papers will be read as the entire program is one of demonstrations in the field operation of the Medical Department. The members attending will live at the post and the expense will be very slight.

PERSONALS

PAUL J. ZENTAY, M.D., F.A.P.H.A., of St. Louis, was recently elected president of the Missouri Social Hygiene Association, succeeding Dr. Llewellyn Sale.

DR. FRANK A. TINKER, Health Officer of Lapeer, Mich., was given a banquet by the Lapeer County Medical Association recently in honor of his completion of 50 years in the practice of medicine. For the last 10 years he has been city health officer.

GRACE ABBOTT, member A.P.H.A., for 13 years Chief of the Children's Bureau, Washington, D. C., resigned her office recently, effective July 1. Miss Abbott will go to the University of Chicago to become Professor of Public Welfare Administration.

WILTON L. HALVERSON, M.D., member A.P.H.A., of Los Angeles, Calif., has been appointed Health Officer of Pasadena, Calif., succeeding Dr. Jay D. Dunshee, member A.P.H.A., who is now Health Director of the California State Department of Public Health.

GEORGE J. WHERRETT, M.D., member A.P.H.A., of Ottawa, Ont., Canada, has been appointed executive secre-

tary of the Canadian Tuberculosis Association. He succeeds Dr. Robert E. Wodehouse, member A.P.H.A., who was recently appointed Deputy Minister of Health in the Department of Pensions and National Health at Ottawa.

DR. W. W. PETER has been appointed Director of Medicine and Health of the Navajo Indian Reservation, under the U. S. Bureau of Indian Affairs. His address is Gallup, N. M.

DR. IRVING S. CUTTER, Dean of the Medical School, Northwestern University, Chicago, was appointed health editor of the *Chicago Tribune*. He succeeds Dr. William A. Evans, F.A.P.H.A., Tribune health editor since 1911, who is retiring.

MARGARET SANGSTER, young Navajo trained nurse, is the first full-blood American Indian public health nurse to go out to work among her people, under assignment of the Indian Bureau, to one of the Navajo community centers being developed under the new Indian policy instituted by the present administration. She recently finished her year of public health study at the Henry Street Settlement. Miss Sangster was born on the Navajo Reservation, was educated in an Indian Boarding school, and was then graduated in nursing from the Methodist Hospital in Los Angeles. For 3 years, following her graduation, she served as a nurse in the Indian Service at the Carson School Hospital in Stewart, Nev.

LEONARD GREENBURG, M.D., Fellow A.P.H.A., of the Yale University School of Medicine, New Haven, Conn., has been granted six months' leave of absence to take an appointment as acting Health Officer of the City of New Haven, in place of Dr. John L. Rice, now Health Commissioner of New York City. A permanent appointment is impossible at present on account of a city ordi-

nance requiring a year's residence for all appointees to municipal positions. Since there are no qualified candidates in New Haven who are able to take the position on a permanent basis, it is hoped that the ordinance may be modified before the end of the year.

CONFERENCES

Aug. 6-10, Annual Meeting of the American Dental Association, St. Paul, Minn.

Aug. 13-18, Twelfth International Veterinary Congress, New York, N. Y.

Aug. 15-24, Educational Exposition and Conference, under the auspices of the National Association of Public School Business Officials, New York, N. Y.

Aug. 31-Sept. 3, Third Institute on Health Education, under the auspices of the American Public Health Association, in connection with its 63rd Annual Meeting, Pasadena, Calif.

Sept. 2, State Laboratory Directors' Conference, for Directors of State Laboratories and their principal assistants only, University Club, Pasadena, Calif.

Sept. 3-6, 63rd Annual Meeting, American Public Health Association, Pasadena, Calif.; headquarters, Huntington Hotel and Maryland Hotel.

Sept. 4-6, 9th Conference of the International Union Against Tuberculosis, Warsaw, Poland.

Sept. 10-13, 13th annual scientific and clinical session of the American Congress of Physical Therapy, Philadelphia, Pa.

Oct. 8-10, Annual Meeting of the Association of Military Surgeons of the United States, Medical Field Service School, Carlisle Barracks, Pa.

Oct. 15-18, 17th Annual Meeting of the American Dietetic Association, Washington, D. C.

Oct. 15-19, American College of Surgeons, Boston, Mass.

Nov. 13-16, Southern Medical Association, San Antonio, Tex.

Dec. 27-30, Annual Science Exhibition of the American Association for the Advancement of Science and Associated Societies, Pittsburgh, Pa.

April 29-May 3, 1935, 19th Annual Clinical Session of the American College of Physicians, Philadelphia, Pa.

"How often should we SHAMPOO?"

"Once a week with DERBAC", say medical authorities—especially during the dusty summer and fall months.

Use DERBAC in *Silver* package for dandruff and pediculosis. *Gold* package for general shampooing. Send 10c for 25c size trial cake.

Epidemic Cerebrospinal Meningitis in China

WILLIAM W. CADBURY, M.D., F.A.C.P.

Canton Hospital, Canton, China

EPIDEMIC meningitis like some other diseases has been considered to be relatively less common in China than in the West. It was interesting therefore to discover that several epidemics have already been reported extending over a wide range of the country, and as scientific medicine becomes more general the disease will, we believe, be found as prevalent in China as elsewhere in the world.

PAST INCIDENCE IN CHINA

The most complete epidemiological data at hand are those of the Health Department of the Shanghai Municipal Council.¹

In 1898 Dr. Arthur Stanley reported 3 deaths in the foreign community, from acute meningitis. There were none in 1899, 1 in 1900, 2 in 1901, and 1 in 1902. From 1903 to 1917 no cases were reported. From 1918 to 1928 there were a few deaths annually, there being 76 in 1920. In 1929 came the severe epidemic with 1,099 reported cases and 403 deaths. In 1930 and 1931 there was a marked drop (Table I).

For Hongkong² my references go back only to 1909, and from that year

to 1917 no cases were reported. In 1918 came the great epidemic, followed in succeeding years by a gradually falling incidence (Table I). For Macao I have depended entirely on the report of the 1932 epidemic by Dr. Perigrino da Costa.³ Only a few scattering cases are reported from 1918 to 1931 (Table I).

The history of the disease in Canton is veiled in obscurity except in so far as hospital reports go. In my own experience in Canton there has never been a serious epidemic of the disease. However, a personal note from the city department of health declares that in 1930 there were 257 cases reported with 223 deaths, and in 1931, 77 cases and 9 deaths. One must question seriously the accuracy of these data, because inquiry at the various city hospitals during those years showed that only sporadic cases were seen (see also Table I under Canton Hospital).

Many cases of convulsions in children and tuberculous meningitis in adults have been erroneously diagnosed epidemic meningitis.

The National Epidemic Prevention Bureau's Monthly Returns by Provinces, which, though my files are very

incomplete, report the disease from all of the 18 provinces except Kansu, from which many data are lacking.

PREVIOUS EPIDEMICS IN CHINA

Attention was first forcibly drawn to the occurrence of the disease in China by the Hongkong epidemic of 1918.^{1,2} The first case was reported February 9, but there had probably been cases in January. The maximum incidence occurred in March, after which there was a rapid decrease during April. There were reported 1,232 cases with a mortality of 76 per cent. During this period no cases were officially reported in Canton, but during the year there

was 1 fatal case admitted to the Canton Hospital.

The next important epidemic was that reported by Stevenson and Tang,⁶ who reported 700 to 800 cases occurring in Luchowfu, Anhwei Province, in 1919-1920. The maximum incidence was in February and March, a sudden change from warm to cold weather, with rain, causing a definite increase. Chief reliance was placed on spinal puncture, the average number per patient being only 3, while many had only 1. The mortality of untreated cases was estimated at 40 per cent; of the treated cases only 5 per cent.

A third important epidemic occurred

in Shanghai in 1929.⁷ It reached its height in the third week of April and there was a mortality rate of 46.4 per cent.

MENINGITIS IN 1932

When news came of the epidemic in Macao, many inferred that it had been carried by the thousands of refugees who poured into Macao, Hongkong, and Canton following the Japanese attack upon Shanghai. I therefore wrote to the Commissioner of Public Health of

the Shanghai Municipal Council, who replied June 9, 1932:

I have to state that in my opinion cerebrospinal fever has not been epidemic in Shanghai this year. . . . In regard to meningitis as a whole, it may be of interest to note that there is clear evidence this disease is not usually spread from Shanghai, but spreads to it from surrounding districts, or at any rate this was so during the last epidemic. . . . In regard to the theory that refugees from Shanghai spread meningitis over other portions of the country, I have to state that I cannot see any grounds for this at all. For some reason or other the theory that Shanghai

CHART B—Hours of sunshine, maximum and minimum temperature (Centigrade) compared with the daily and weekly incidence of meningitis at 7 Canton hospitals during February, March, and April. Estimation is made as of day of onset of the disease.

acts as a reservoir for communicable diseases is a favorite one but is not, in my view, supported by evidence.

From January 2 to June 4, 1932, there were only 71 cases reported from Shanghai by the Commissioner of Health, among the resident population, although 58 additional cases among the non-resident population had occurred.

In Macao meningitis assumed truly epidemic proportions a detailed report of which has been prepared by Dr. P. J. Peregrino da Costa.³ By referring to Table I it will be noted that no epidemic had been previously recorded in the colony. The origin of the 1932 outbreak is unknown, but the disease was rampant in some of the country towns of the neighboring district of Chung Shaan. He suspects that refugees from North China, passing through Macao, brought the disease. The second case was a boy, who had

arrived 2 days previously from his native village. Other early cases apparently contracted the disease in Macao. Altogether some 600 cases occurred, in a population of over 100,000, but only 503 were proved.

In Hongkong 207 cases were reported, but the origin of the first cases has not been determined.

With regard to Canton, the data are, of course, far less reliable, and we have collected statistics from several of the leading hospitals in the city in addition to the cases reported by the health department. That these latter figures are only in part reliable is proved by the excessive numbers reported in 1930, when there was no epidemic apparent to workers in the different city hospitals.

For the 1932 epidemic I prepared a questionnaire which was distributed to the chief hospitals in Canton and vicinity. Data were asked for as to the

number of patients seen, with time of onset, duration of disease, and result; also age and sex of patients, number of spinal punctures made, cell count of spinal fluid and white blood cell count, amount of serum given, the occurrence of meningococci, and the presence of Kernig's Sign, headache, stiff neck, eruption, convulsions, and delirium; what measures appeared to be most beneficial in treatment, *i.e.*, spinal puncture, serum and others, and the origin of the epidemic.

Satisfactory replies were received from Canton Hospital, First Sun Yat Sen, David Gregg, Kwong Wah, Leung Kwong, and Kong Tsuen Hospitals. Brief statements were obtained from the Municipal Hospital and Dr. Todd.

From this information and the data from the Health Department, we are able to give the incidence of the Canton epidemic in relation to its appearance in other cities.

By reference to Tables II and III and to the Chart A, one can note that the epidemic appeared first in Macao, beginning in February, reaching its peak in March, and subsiding in April, after which month hardly any cases appeared. The same was practically true of those reported in 7 Canton hospitals where many cases occurred from March 6 to April 16, whereas the Canton Health Department showed the maximum about the middle of April. Cases are reported a week or more after their entrance to the hospitals, and for the 7 hospitals the time was estimated from the day of onset.

The Hongkong Health Department reports a maximum incidence in the middle of April, gradually diminishing in May and June. Thus the disease began in Macao, and was followed a little later by an outbreak in Canton, and the following month in Hongkong. In Shanghai the disease was never very prevalent, but in April and May the highest incidence occurred.

METEOROLOGICAL CONSIDERATIONS

Olitsky⁵ in his description of the 1918 epidemic in Hongkong states that the temperature had a marked influence on the incidence of the disease. When there occurred a sudden drop in the temperature the number of cases increased, and *vice versa*—the increase occurring about 4 days later. The influence of sunshine was also noted, a lack of it being followed by an increased incidence in the disease. Humidity and rainfall had little influence.

da Costa,³ in the 1932 epidemic in Macao, noted that whenever there occurred a pronounced difference between maximum and minimum temperatures on any given day, the number of cases increased after a few days, and concludes that humidity, rainfall, and lack of sunshine have little bearing on the incidence of the disease.

For the Canton cases we have charted (Chart B) the daily and weekly incidence, together with the daily records for hours of sunshine and maximum and minimum temperature, obtained at the Freeman Meteorological Observatory, Lingnan University. The week ending February 27 showed the first decided rise in incidence, following 4 sunless days and a precipitous drop in the temperature to 4°. A week later the temperature rose and there were several sunshiny days. The incidence remained the same. In April there were 2 weeks of sunless days, but moderate temperatures were followed by a gradual decline.

In February there were 12.99 cm. of rain, in March 9.9 cm. and in April 13.41 cm. The average humidity in February was 68 per cent, in March 79 per cent and in April 87 per cent.

The latitude of Shanghai is between 31° and 32° N. The latitudes of Canton, Hongkong, and Macao lie between the Tropic of Cancer and 22° N.

The available data do not reveal any striking correlation between the mete-

TABLE III
INCIDENCE OF DISEASE ACCORDING TO MONTHS IN 4 CITIES 1932

Month	Canton Health Dept.	Seven Canton Hospitals	Shanghai (Residents only)	Hongkong	Macao
Jan.	6	4	12	5	1

Nov.	1	0		7	0
Dec.	1	1		8	0
Totals	174	101	107	207	505

orological conditions and the rise and fall of the epidemic.

Sex—In the 7 hospitals there were 107 patients whose sex was reported. Of these 60, or 56 per cent, were males, and 47, or 44 per cent, females. In Macao 59 per cent and in Hongkong 65 per cent were males. At the Canton Hospital, of the 31 cases treated 71 per cent were males.

Age—The ages were recorded in 84 patients in 5 general hospitals in Canton: 10–20 years, 40 cases; 21–30 years, 21 cases; under 10 years, 19 cases (1 under 6 months); 31 and over, 4 cases.

It will be noted that nearly one-half of all the cases occurred in the 2nd decade, and one-fourth in the 3rd. Most of the remainder were under 10 years, but few were infants.

At Macao, most of the patients were under 10, but the 10–20 year group

were nearly as numerous. In the 3rd decade there were less than one-half the number in the 2nd, and in the 4th decade about one-half those in the 3rd. There were few over 40 years of age.

In the Hongkong epidemic of 1918, the peaks of the curve of incidence, according to age, were from infancy to 5 years and at 17½ years of age.

Duration of Illness—Most of our cases at Canton Hospital as well as in other hospitals were brought in on the 2nd to 4th day of illness, and all cases

TABLE IIIA

<i>Duration of Illness</i>	<i>Number of Cases</i>
2–5 days	26
6–10 days	28
11–15 days	10
16–20 days	15
21–30 days	10
31–40 days	5
41–50 days	3
over 50 days	7

had been ill more than 24 hours. Taking the records of 7 Canton hospitals, the total days of illness are distributed as shown in Table IIIA.

The periods of 6 to 10, and 2 to 5 days, were the most usual: 9 cases each were ill 4 and 6 days. One patient was reported as cured after 87 days, and 1 of the Canton Hospital cases suffered a relapse, but finally recovered after 46 days. We may say that recovery usually requires from 1 to 3 weeks.

Death usually occurred in less than a week after the onset.

MORTALITY STATISTICS

The death rate varies enormously in different epidemics.

In the Anhwei cases⁶ the mortality was estimated as 40 per cent for untreated cases and 5 per cent when a simple spinal puncture was performed. In the 1918 Hongkong epidemic the mortality was 76 per cent in spite of serum treatment and spinal puncture. In Shanghai, 1929, there were 46.4 per cent deaths. In 1932, Macao reports a death rate of 59 per cent in the 491 cases which entered the Isolation Hospital. The Medical Department of Hongkong reports a mortality rate of 58 per cent in 1932, while Shanghai had a death rate among residences of the settlement of 55 per cent. The Canton Health Department reported 21 per cent deaths.

In 6 of the Canton Hospitals, from January until June, including the period of the epidemic we have:

	Number of Cases	Deaths
Canton Hospital	26	5
San Yat Sen	26	12
Kwong Wah	14	4
Leung Kwong	14	7
Municipal	6	2
Total	86	30 = 34 %

These cases were nearly all verified bacteriologically.

The death rate among later sporadic cases was greater than during the epidemic. At Canton Hospital there were 6 cases from June to September with 4 deaths.

Most fatal cases had been sick but a few days before admission and did not live long. Of 34 deaths in 5 hospitals, 11 had been sick 1 day before admission, 5, 2 days, and 7, 3 days. There were 2 each who had been sick for 4, 5, 6, and 7 days, 1 for 10 days, and 2 for over 14 days.

In Macao of 290 deaths, 63 died on the day of admission and 112 from the 2nd to the 5th day.

Spinal Puncture—This was always done in the lumbar region. It was usually done only once a day, and as symptoms abated, every other day or less frequently, depending on the temperature, the number of cells in the spinal fluid, headache, stiffness of the neck, etc.

At Canton Hospital no case was diagnosed epidemic meningitis unless a spinal puncture had been made and purulent fluid obtained. During the height of the epidemic a child was brought in with high fever, a very stiff neck, and severe headache. Spinal puncture was done and clear fluid obtained under increased pressure. The cell count was not increased. The next day the child showed typical signs of mumps, from which he made an uninterrupted recovery.

One case was punctured 16 times in 51 days and made a good recovery. A sporadic case was punctured 25 times during 41 days and also recovered. In the other Canton hospitals 18 was the highest number of punctures made, 2 or 3 being usual.

In the writer's opinion this procedure is by far the most important means of relieving symptoms and bringing about a cure. Dr. Valentine of Hongkong writes: "No improvement was observed in any case, unless lumbar punc-

ture had been performed." Dr. S. W. Phoon of Tung Wah Hospital, Hong-kong, reported that an average of 5 punctures were done per case when treatment was started early.

Spinal Fluid—The spinal fluid in true epidemic meningitis sooner or later becomes cloudy, due to the large number of leucocytes. This is important in the differential diagnosis from tuberculous meningitis, so common in South China. The number of cells, is, we believe, of definite value in determining the progress of the disease and as an indication for further punctures. In 24 of our cases diagnosed epidemic meningitis, meningococci were found. In these the maximum cell count was 3,900, and the minimum 730—average of 1,000 to 2,000. At the Kwong Wah Hospital counts of 15,000 to 18,000 were made. At the Sun Yat Sen Hospital, counts varied in positive cases from 32 to 5,120 cells.

The white blood cell count was invariably raised in the acute cases. In 5 hospitals there were 68 cases in which meningococci were demonstrated and in whom a leucocyte count of the blood was made. Deaths in these cases are shown in Tables IV and V.

TABLE IV

No. of W.B.C. in Blood	No. of Cases	No. of Deaths	% Deaths
9,000 or under	3	3	100%
10,000-14,000	28	6	21%
15,000-19,000	21	9	43%
20,000 and over	16	5	31%

The lowest white count, 7,600, was in a fatal case in whom meningococci were not found. One malignant fatal case had a leucocyte count of 38,000 cells and the spinal fluid was blood-tinged, but contained no meningococci. Of the positive cases the highest leucocyte count was 36,000, and this patient recovered.

We conclude that a white blood cell count of 10,000 to 14,000 is most

favorable; a lower count is very grave, and one above 15,000 is serious, but not so bad as the lower count.

OCCURRENCE OF MENINGOCOCCI

Naturally the presence of the organism in the spinal fluid is essential for making an absolute diagnosis of epidemic meningitis. On the other hand, it might be assumed that a case belonged to the epidemic variety: (1) when the spinal cell count exceeded 500; (2) when no other organisms could be found; (3) if the case recovered; in spite of the fact that repeated smears of spinal fluid failed to show the intracellular diplococci.

Thus a positive diagnosis was justifiable in several negative cases. Table V shows the percentage of positive cases in each hospital, judged by presence of meningococci.

TABLE V

Hospital	No. of Cases	No. Positive
Canton Hospital	31	24
Sun Yat Sen	23	19
Kwong Wah	14	14
Leung Kwong	14	13
David Gregg	13	8
Kong Tsuen	3	3
Total	98	81

About 83 per cent of the cases showed a positive bacteriological finding. In 1 of the hospitals all cases were positive. At Canton Hospital 17 per cent had a positive spinal fluid. In negative cases a search was made for the tubercle bacillus and pus forming organisms, without results, though there were, during 1932, several cases diagnosed tuberculous meningitis, in which the spinal cell count was relatively low and tubercle bacilli were demonstrated, or else no organism was found. All ended fatally.

CLINICAL SIGNS

The occurrence of the common clinical signs is recorded in Table VI.

It will be noted that of the 97 cases in 7 hospitals, 90 were reported with Kernig's sign, but it has been our observation that this is practically always present in genuine cases.

Delirium was recorded in 69 cases, but in 4 the absence was questionable. When a patient is at all conscious, stiffness of the neck is generally present.

Eruptions were conspicuous by their absence. Four cases with purpura were seen at the Sun Yat Sen Hospital, and 18 altogether in the series.

In Macao 50 per cent of the hospitalized cases had convulsions or delirium. There was only 1 case with a purpuric eruption.

Dr. S. W. Phoon reported on 75 cases observed at Tung Wah Hospital in Hongkong and states that Kernig's sign was present in all. Delirium and convulsions were rare, stiff neck was common.

TREATMENT

The one form of treatment of undisputed value is frequent lumbar puncture. Various palliative remedies for

control of restlessness and pain are of course to be utilized.

Serum was generally employed in our patients, but the actual benefit from its use may be questioned. The number of spinal punctures varied from 1 to 25. The amount of serum at each dose varied from 10 c.c. to 40 c.c.—usually 20 c.c.—the total amount from 10 c.c. to 285 c.c.

Thus the majority of patients treated in Canton were given one form or another of antimeningococcic serum. I have found none of the Canton doctors very enthusiastic over its therapeutic value, aside from the effect of spinal puncture alone. The sera used were all polyvalent.

SUMMARY

1. Epidemic cerebrospinal meningitis first manifested itself in China in epidemic form at Hongkong in 1918. It became more severe in the 4th week of March and continued to be prevalent until the 2nd week of May. Other epidemics have been reported from Anhwei in 1920 and Shanghai in 1929.

TABLE VI
CLINICAL SIGNS

Name of Hospital	Cases Reported	Kernig's Sign	Headache	Delirium	Stiff Neck	Convulsions	Eruption	
Canton Hospital	31	27	29	17	27	6	1	
Sun Yat Sen	23	23	23	16	17	3	5	4 purpura
Kwong Wah	14	11	13	10	11	9	2	
Leung Kwong	14	14	14	11	14	8	5	
Municipal	6	6	6	6	6	6	4	
David Gregg	6	6	6	6	6	3	0	
Kong Tuen	3	3	3	3	3	3	1	
Total	97	90	94	69	84	38	18	

2. In 1932 the disease appeared in Macao in epidemic form for the first time in the 4th week of February. It reached its height in March, subsiding during April, and practically ceased early in May.

3. For Canton, according to Health Department statistics, the disease began to increase in the 1st week of March, and continued to be prevalent until the middle of May. Reports from 7 Canton hospitals indicate that the epidemic began in the 3rd week of February and lasted till the end of April.

4. The meteorological conditions in Canton seemed to have little effect on the epidemic.

5. Spinal puncture is essential for accurate diagnosis. It is the most effective therapeutic measure available.

6. Polyvalent anti - meningococcic

serum was generally employed intravenously, intramuscularly, and subcutaneously. No especial advantage was noted for these latter methods over the intrathecal. Several brands of serum were employed with no particular preference for any one.

Johann Peter Frank

DIFFICULT as it is to make a critical study of as vast a work as the "Medizinische Polizey" it is yet more difficult to write an appreciation of it. Although the "System" is judged to be the first modern comprehensive attempt to codify the details of public health administration, little attempt has been made to trace what influence it may have had on the subsequent history of public health. To judge whether Frank was more than a curiosity, a man whose ideals were thoroughly modern but who had little influence, is a major problem in itself. The analyses of his ideas given in this paper can make possible such an evaluation.

To elaborate praises of Frank's penetrating thought, his vision, and his scholarly treatment of his subject would be useless. If these things do not speak for themselves no one can speak for them. To assume a condescending

air and smile at his faith in the power of legislation, his inclusion of much superstition and prejudice with the more enduring matter of his discussion, would be equally useless. Kratter¹ in 1888 made an observation which will perhaps serve better as epilogue than anything else which could be said:

If anyone has leisure and desires to refresh himself with a language which has not yet buried thought beneath a professional idiom but still conveys it without embarrassment or reservation, and if anyone enjoys a frank delineation of social conditions—let him read Frank.—By Leona Baumgartner and Elizabeth Mapelsden Ramsey, *Annals of Medical History*, Vol. 6, No. 1 (Jan.), 1934, p. 83.

Relation of Soil Fertilization with Superphosphates and Rock Phosphate to Fluorine Content of Plants and Drainage Waters*

E. B. HART, PAUL H. PHILLIPS, AND G. BOHSTEDT
*Departments of Agricultural Chemistry and Animal Husbandry,
University of Wisconsin, Madison, Wis.*

THERE is a widespread interest in fluorine in relation to human and animal life because of its known toxicity and production of mottled teeth in man¹ when ingested in too great a concentration with drinking water. It is well known that rock phosphate from any source contains about 3.5 per cent of fluorine. The application of 1,000 lb. of this material to an acre will add 35 lb. of fluorine. In the prevailing sulphuric acid method for the manufacture of superphosphate, a part of the fluorine is lost or reduced by virtue of dilution with calcium sulphate. Analysis of commercial superphosphate shows a fluorine content of about 1.86 per cent. The fluorine content is about one-half that of rock phosphate.² Where electric furnace methods of manufacture of superphosphate—fusion with silicon and carbon—are used, the product is practically free from fluorine. This product finds its use in such materials as baking powders and pure chemicals.

It has been the practice in this and other countries since the development of the mineral theory of plant nutrition

to fertilize our soils with superphosphates, and more recently to use the rock phosphate directly. Hopkins³ at the University of Illinois, was a strong advocate of the direct use of rock phosphate in soil building, advocating applications of 1,000 to 2,000 lb. per acre every few years.

Because of our interest in the fluorine problem growing out of an extended investigation of the effect of feeding rock phosphate to animals, we undertook an investigation of the effect of continued fertilization with fluorine-phosphate carriers on the fluorine content of plant materials and drainage waters. There are several agricultural experiment stations in this country where fertilization with rock phosphate, superphosphate, and bone meal has been in progress for a quarter to half a century, and it was to these stations that we sent in 1933 for the plant materials. We had the coöperation of the stations of Illinois, Indiana, Ohio, Pennsylvania, Tennessee, and Wisconsin.*

From the Ohio Station we secured

* Published with the permission of the Director of the Wisconsin Agricultural Experiment Station.

* Our thanks are due to Dr. Burlison of Illinois, Dr. Wiancko of Indiana, Dr. Barnes of Ohio, Dr. Gardner of Pennsylvania, Dr. MacIntire of Tennessee, and Dr. Musbach of Wisconsin, for their coöperation in securing these samples.

materials from plots that had had rock phosphate treatment for 36 years. Seventeen years of treatment was the shortest period for any plot record. The materials collected consisted of wheat and oats in two cases, plus wheat straw, oat straw, alfalfa, cow pea hay, and mixed hays. The samples were analyzed on an air-dried basis, and the fluorine is expressed in milligrams of air-dried material per kilo. The analysis was made by Armstrong's modification of Willard and Winter's method.⁴ The results are given in Table I.

In one column there is an estimation of the amount of fluorine per acre received by the rock phosphate treatment during the entire period of fertilization, varying from 326 lb. in 17 years on the Illinois plot to 60 lb. on the Pennsylvania plot. The estimate is based on the amount of rock phosphate applied and an assumed fluorine content of 3.5 per cent. No estimation was made of the fluorine contributed by the other fertilizers.

There is considerable variation in the fluorine content of these plant materials, from 0.26 mg. per kilo in the wheat grain grown on the bone meal plot of Tennessee, to 2 mg. per kilo in the alfalfa grown on the superphosphate plot at Marshfield, Wis. One factor in this variation is the soil type and its geology. One can find little evidence from the data that the application of rock phosphate or acid phosphate has consistently increased the fluorine content of the plants above that of plants grown on soils receiving bone meal or a low fluorine application. In some instances the plan of fertilization involved the application of phosphorus in equivalent amounts, which makes it probable that in such cases the amount of fluorine added was as high in the superphosphate application as in the rock phosphate treated plots.

In no case had the level of fluorine

in the plant tissue analyzed risen to the point of making it dangerous as a source of food for animals. The highest recorded fluorine content was 2 mg. per kilo in alfalfa grown on the superphosphate treated soil at Marshfield, Wis. A cow consuming 20 kilos daily of such roughage would ingest 40 mg. From extensive work at this station the upper limit of safety for a dairy cow is 2.5-3 mg. of fluorine daily per kilo of body weight, or 1,000 to 1,200 mg. These data apparently place the plant tissue analyzed from the rock phosphate and superphosphate treated plots beyond the suspicion of imparting any serious element of danger when used as food materials. What a longer period of application may do should be studied.

Since the plants growing on these high fluorine plots had not shown significant or dangerous increments of fluorine in the periods studied from the standpoint of animal nutrition, we turned to a study of the influence of such fertilization on the fluorine content of drainage water. Fortunately we had the coöperation of Dr. MacIntire, of the Tennessee Agricultural Experiment Station, Knoxville, where lysimeters are in operation under different soil treatments. In January, 1934, following a period of drought, we secured from Dr. MacIntire three samples of water draining through Chickamauga limestone, untreated and treated with superphosphate and rock phosphate. Three additional samples of water from the same plots were sent May, 1934. The soils received the phosphate treatment beginning in 1930 and continued annually through 1933. The annual treatment was made on the basis of 96 lb. of P_2O_5 equivalence per acre. We calculated that this application in the case of rock phosphate during the 4 years has been about 53.7 lb. of fluorine per acre. The data are given in Table II. The analyses were

made by the same method as used for the plant tissue.

The data indicate that the phosphate treated areas have led to a marked increase in the fluorine content of the drainage waters, particularly the rock

phosphate treated soil. Possibly in both instances—rock phosphate and superphosphate treatment—the fluorine largely escapes into the drainage water, but its rate of escape may be related to its original availability. To answer such questions periodic analyses would be necessary. In one instance—rock

phosphate treatment—the concentration of fluorine in the water (1.7 mg. per liter) approached the level recorded as sufficient to induce mottling in teeth,¹ namely, 2 mg. per lit. This figure may be unusually high due to the preceding drought and possible concentration of the fluorine in a limited drainage volume. The total volume of drainage water of a year or more and the fluorine concentration therein would be a more accurate method of gauging the degree of contamination. However, if in a 40 in. rainfall there were an actual drainage volume of 10 in., the concentration of fluorine per lit. could amount to 6.3 mg. if all the fluorine were dissolved in the drainage water and the application of rock phosphate had been 400 lb. per acre—not an unusual application.

DISCUSSION

These data raise the question whether our present systems of soil fertilization with fluorine-carrying phosphates may lead to a contamination of drinking waters to a point where they may become dangerous to human health. No attempt is made from these limited data to give an answer, our only purpose being to call attention to it. Already health authorities are making tests for fluorine in public drinking

supplies, for the most part qualitative and not quantitative. No attempt, so far as we know, has been made to trace the origin of this fluorine contamination. It no doubt comes from the phosphorite-bearing rocks of the drainage areas. No one would suppose that the more recent recognition of fluorine as a deleterious contaminant of drinking water when in too high a concentration is in any way associated with phosphate fertilizer application, which has neither been of long duration nor on an extensive scale except in limited localities. Is there danger in a century or two of such application? Should public health warrant it, there is probably no reason why phosphate fertilizers cannot be prepared by methods already available that could largely eliminate fluorine contamination—the electric furnace and fuel-fired furnace processes, both of which are able to produce a phosphate of low fluorine content. Cheap power and public demand may be important factors in bringing about this change if it should prove necessary.

SUMMARY

1. Plant materials from plots receiving fluorine-carrying phosphates, such as rock phosphate and acid phosphate, for periods of 16 to 36 years did not show consistent or greatly increased fluorine content over plant materials grown on plots receiving a low fluorine carrying phosphate such as bone meal.

2. Drainage water from a single series of lysimeters in Chickamauga soil at Knoxville, Tenn., showed a particularly high fluorine content where the soil had been treated with rock phosphate, and a definitely increased fluorine content when treated with superphosphate as compared to the control.

3. These results in respect to drainage water raise the important question as to the ultimate influence of our present system of fertilization with rock phosphate or superphosphate as now manufactured upon the fluorine content of drinking waters and their relation to public health.

4. With our limited available data nothing further is intended in this article than to call to the attention of public health officials,

I am wondering if universal service will be as efficient.

I am wondering if we, as health workers, have failed in our educational efforts, and public appreciation of the care of disease is greater than its prevention.

I am wondering if all our ideals of public health administration and service are incorrect, and we are not keeping abreast of social changes and present-day exigencies.

I am wondering if in our anxiety to maintain our existence and in our envy of those who are receiving large sums of emergency relief funds we are willing to sacrifice the ideals built up by tried and proven experiment.

I am wondering if this proposal to place medical relief activities under public health auspices is not, after all, a tribute to the sociological training and organizing ability of public health leaders; but—

I am wondering if it does not mean that we are to be relegated to the position of "Doctor Bull" of several decades ago.

Is Cancer Becoming More Prevalent?

THAT diseases like cancer, diabetes and diseases of the heart and arteries, all of which are associated with the older ages, should show an increase in the registered death rates is natural, for there has been a marked aging of the population. In New York City, for example, the proportion of persons over 45 years of age is now one-third greater than it was only a generation ago. No one denies that this aging of the population has brought with it an increase in the death rate of the diseases associated with the older ages. But as the heading of this article is usually interpreted there are those who believe that, apart from the age factor, some or all of the diseases mentioned above have actually become more prevalent in recent years.

The actual number of deaths involved in cancer, diabetes, and diseases of the heart and arteries is so great that a real increased prevalence, beyond that due to aging of the population, should manifest itself by an increase in the specific death rates in the higher age groups. However, when we examine the specific death rates for New York City

no such increase can be discovered. In fact, the specific death rates, even in the higher age groups, show a decline during the past thirty years.

It is instructive to analyze the course of our cancer death rate, not for all forms of cancer, but, as is done below, for "visible" and "other" forms of cancer. In this way we deal with one of the important factors which must be reckoned with, namely, diagnosis. Under the heading "visible" cancers we have included cancer of the skin, breast, buccal cavity, and female genitals. Some idea of the number of deaths involved under the term "visible" cancers can be gained from the following figures showing such cancer deaths during the three years 1929-31:

	Males	Females
Cancer of the skin	212	81
Cancer of the breast	32	2,158
Cancer of the buccal cavity	718	111
Cancer of female genitals	2,651
Total	962	5,001

The graph tells its own story. Whereas the death rate charged to cancer generally shows an upward trend

during the past 30 years, the death rate from "visible" cancers shows practically no change. If cancer were actually becoming more prevalent in the various age groups, it would be strange

not to have the visible cancers participate in this increase. . . .—Charles Bolduan and Louis Weiner. *Quart. Bull.*, Dept. of Health, New York, N. Y. 11, 1, 1934.

Dermatitis in the Oil Refining Industry*

LOUIS SCHWARTZ, M.D.

Senior Surgeon, U. S. Public Health Service, New York, N. Y.

THIS paper is based on a study of 8 oil refineries employing about 14,000 men, of whom 4,500 were actually examined for the occurrence of dermatitis, and also on the sickness records of 11,000 of them over a period of 2 years.

The refineries studied used all varieties of crude oil obtained from North and South America, such as Pennsylvania, California, Ranger, Mid-Continental, Mexican, Peruvian, Venezuelan, and Texan. These crudes are classified as having paraffin, asphalt, naphthenic or mixed bases, and their character, as well as the final products desired, determines the refining process.

There were no marked differences in the skin conditions found in the various refineries using different crudes, except in those refineries where a paraffin base crude was used in the manufacture of paraffin.

PROCESS

The crude oil is distilled in batteries of stills and a number of cuts are made at different times in the process. Coke is the final residue in the still except where an asphalt base crude is used.

To remove various deleterious products from the distillates they are treated with sulphuric acid, caustic soda, fuller's earth, liquid sulphur dioxide, and sometimes "sweetening" with litharge and flowers of sulphur, or with

sodium hypochlorite and chloride of lime.

Paraffin is obtained from the paraffin distillate of a paraffin base crude by passing it through a cooled plate press where the wax collects on the plates. The press is then opened and the wax is scraped off by hand, then purified by repeated "sweating" and by passing through bone black.

Some refineries manufacture various by-products, such as insecticides, greases, and wax products. The insecticides are made by using extract of pyrethrum flowers in various petroleum distillates. Greases are manufactured by mixing soap and lubricating oil in various proportions. Candles are made of paraffin by molding, or by dipping wicks repeatedly in the molten paraffin until the required thickness is acquired. Aniline dyes are used for coloring. No cases of dermatitis were observed in either the grease or the candle making, but many cases of dermatitis occurred in the manufacture of insecticides, due to hypersensitivity to pyrethrum flowers.

PRESENT SURVEY

The sickness records showed that 196 cases diagnosed as industrial dermatitis occurred among 11,000 workers during the period of 2 years.

In 1 refinery, where complete records were kept, of 16,000 treatments, 202 were skin cases which may have been of industrial origin, or about $1\frac{1}{4}$ per cent, and 128 skin cases that were diagnosed as not of industrial origin.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 10, 1933.

In the present survey, 488 skin conditions were found, of which 25 were distinctly not of industrial origin.

The chief skin hazards in oil refining seem to be burns from explosions and fires, or from acids and alkalis. Oil acne and papillomata, as well as an excessive amount of epithelioma, result from oil and paraffin.

About 10 per cent of those examined showed on the dorsum of the hands and on the forearms, and sometimes even on the legs, many pin-head to pea-size flat, small, pigmented papillomata. These occur in greater proportion among machinists, mechanics, and laborers, whose hands are usually covered with oil, grease, and dirt. A similar condition has been described as occurring in about 25 per cent of men working in Dutch briquette factories.

Telangiectatic spots were found on the exposed parts of the skin of many of the laborers. They were from pin-head to dime size, and disappeared on stretching of the skin. They are caused by exposure to hot coke when cleaning out the residue from the stills, and also from dipping the hands into hot paraffin during the "sweating" process. It was noted that colored laborers did not show these spots.

Many observers have noted an excessive number of skin cancers among workers in oil and wax. In this study, 12 cases were encountered—3 on the face, 6 on the lip, 1 on the hand, 1 on the ear, and 1 on the scrotum. The last was on a paraffin pressman who also had an epithelioma on the dorsum of the hand.

Three of the refineries examined pressed paraffin, and 81 men who worked on the presses were examined. Characteristic wax warts were found on the hands and forearms of 25 of them. These wax warts differ in appearance from the papillomata described among workers in oil and grease. They are more raised, more verrucous, non-

pigmented, and often occur on the inner surfaces, as well as the dorsum of the forearms and hands.

Among 81 paraffin pressmen, 19 cases of oil acne were found. Oil acne differs from acne vulgaris in that it occurs not on the face, but on the arms, the shoulders, the body, and the legs, and forms around the hair follicle. The lesions of oil acne are elevated, erythematous, indurated, and about pea size, and when they suppurate are known as wax boils. One case of epithelioma of the scrotum was found. This man also had many wax warts on his hands and forearms, one of which was undergoing epitheliomatous changes.

Burns are frequent in oil refineries. They occur from fires, explosions, cleaning hot coke from the stills, and also from the acids and caustics used in the refining process.

When acid tanks are being cleaned of sludge, and in that part of the plant where sulphuric acid is recovered and reconcentrated, acid burns are of frequent occurrence.

The tanks in which the oil and gasoline are neutralized with caustic soda must be cleaned at regular intervals, and caustic burns occur during this process, from contact with the caustic deposited on the sides of the tank. The cleaning of old barrels with caustic soda occasionally causes a dermatitis in a sensitive worker.

Sometimes a worker is met with, who after a number of years of work in the refinery becomes sensitized to gasoline and develops chronic dermatitis.

Epidermophytoses and trichophytides occur among refinery workers, as well as among the rest of the population, and are often mistaken for dermatitis of industrial origin. In the present study no attempt was made to examine the feet of the workers for tinea infections, but 11 cases of tinea of the hands and 1 of monilia infection of the webs of the fingers were found.

PREVENTIVE MEASURES

Most of the refineries provide safety appliances for the prevention of burns from acids, caustics, and coke. These appliances consist of rubber suits, goggles, and gas masks, which the men are compelled to wear when entering acid or caustic tanks. Nearly all of the refineries have shower baths placed throughout the area where acid and alkali burns are apt to occur, so that men splashed can immediately step under the showers. There are also large bath tubs filled with water so that men when burned can be immediately plunged into them.

The burns in coke stills usually occur in the old-style type, where there are manholes through which the men must enter to clean them. These are being replaced as soon as they are worn out with new-style ones in which mechanical means are employed for cleaning out the coke.

The pigmented papillomata occurring among workers in oil and grease could in a large measure be prevented by the compulsory wearing of gloves and compelling the men to wash their hands with soap and water at noon, before eating their lunch and immediately after they stop work for the day.

Oil acne and wax warts among the paraffin pressmen can also be prevented by compelling them to take shower baths, using plenty of soap, immediately after stopping work for the day, and changing to clean clothes. They should also be compelled to have their working clothes washed once a week because they become saturated with oil. In addition to this, the maintenance of an efficient medical and first-aid department, preferably with a full-time medical officer and a registered nurse, physical examination of new employees, and yearly examination of all employees are recommended.

The Controversy About Pasteurized Milk

THE controversy on the pasteurization of milk, described in previous letters, has been continued in the *Times*. A. Bradford Hill, W. W. Jameson and W. W. C. Topley, of the London School of Hygiene and Tropical Medicine, reply to the argument that in a population of 9,000,000 children in this country under the age of 15 only about 4,000 cases of bovine tuberculosis occur annually, or 1 case in 2,200 children per annum. The proportion of children who eventually suffer must be much higher. It can be estimated that between 1 in

100 and 1 in 200 children develop the disease before the age of 15. Milk-borne diseases other than tuberculosis are by no means as negligible as the opponents of pasteurization state. Between 1912 and 1931 there were reported at least 81 outbreaks of various diseases due to milk. In 1929 there occurred a severe epidemic of septic sore throat involving more than 1,000 families, with 65 deaths, and in 1931 an outbreak of 312 cases of paratyphoid fever, with 6 deaths.—London Letter, *J.A.M.A.*, June 23, 1934, p. 2124.

What Can We Learn from Child Health Conditions in Europe?*

RICHARD A. BOLT, M.D., DR.P.H., F.A.P.H.A.

Director, Cleveland Child Health Association, Cleveland, Ohio

REFLECTION upon the evolution of maternal and child care in Europe at once brings to mind our indebtedness to the pioneers in antenatal hygiene, infant metabolism, nutrition, and child sociology. We hold in grateful appreciation the work of a galaxy of European scientists who have laid firm foundations upon which we have builded in the fields of sanitation, preventive pediatrics, and social medicine. Our technics and organization for prenatal centers, maternity benefits, milk stations, infant welfare clinics, day nurseries, nursery schools, and school hygiene bear the original imprint of contributions from abroad. These we have adapted, with minor modifications, to American conditions, and have added certain unique features of our own.

It is not the intention of this paper, however, to dwell upon historical developments. That has been done exceedingly well by others. The purpose here is to sketch in outline present-day conditions and trends in some of the European countries, which may suggest to us ways and means of improving our own maternal and child health.

In Europe child hygiene is considered a definite part of the public health and is integrated with every other health function in the community. The trend abroad in administration of all welfare

measures is decidedly in the direction of public control, concentrating authority in the hands of full-time, technically trained, public officials. Voluntary organizations may, and do, carry on certain phases of maternal and child health work, but always in close cooperation with official agencies.

It is recognized that the first duty of the state is to protect its mothers and children and to promote their welfare. This has been done abroad largely through some form of social insurance, which is undoubtedly one of the strong points of the European system.

An amazing fact in Europe today is the foresight and vigor with which governmental schemes for maternal and child health are being pursued. Wherever we look—in democratic England, bureaucratic France, Fascist Italy, Nazi Germany, Nazi-Fascist Austria, Communistic Russia, or dictatorial Yugoslavia and Poland—similar phenomena present themselves. Whatever the form of government, a desperate struggle is on to preserve, strengthen, and extend services for the welfare of mothers and children. Economic distress appears to be the only inhibiting factor. Mixed motives—humanitarian, utilitarian, socialistic, and militaristic—are discernable; but the net outcome in each instance is more active interest in the health and well-being of mothers and children and more ample provisions for them. In this very fact itself lies a great lesson for America.

* To be read before the Child Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 5, 1934.

England—From the beginning of the 20th century a code of regulations for the health protection of mothers, prospective mothers, and children has been developing in England, Scotland, and Wales. The most recent act—The Children and Young Persons Act of 1932 Amending the Children's Act, 1908—consolidates various public health and welfare measures for children. It extends the powers of health visitors and public health nurses in the welfare schemes. The duties of health visitors and school nurses may be merged and carried out under local authorities. The health visitors may be qualified as midwives, and many of them are performing this function satisfactorily in the counties of England.

There is much better control of midwifery in most European countries than in America. More adequate facilities are available for the training and supervision of midwives. Prenatal and obstetric care is afforded all classes in the population, largely through maternity benefits under National Health Insurance Acts. The central government has recognized also the importance of granting subsidies for maternity hospitals and prenatal clinics and of compensating local physicians when called in by the midwife. In England there are about 55,000 licensed midwives; but only approximately 14,000 are actively practising. This creates a difficult problem in training and supervision and is economically wasteful.

Grants-in-aid from the central government for local maternity and child health work have done much to stimulate better facilities throughout England. These grants originally were made on the "50—50" basis but in 1929 were changed to "block grants" on the basis of local "need" rather than expenditures. There are at present in England 1,300 prenatal centers, 2,800 infant welfare centers, and about 5,000 health visitors and district nurses.

We still have much to learn from Europe in the way of social insurance, especially in its bearing upon governmental subsidies for maternity benefits, child care, tuberculosis, and venereal disease control. While there has been criticism in England concerning certain details of the health insurance scheme, there is no evidence that either the medical profession or the public cares to abandon it. On the contrary, the expressions of opinion which were heard on every hand were in favor of strengthening and extending it.

In England at present there is a great deal of discussion concerning public housing. The relationship between housing and public health is clearly recognized, and definite steps have been taken by the government to wipe out slum areas and to stimulate the building of sanitary houses for the wage earning classes.

In 1933–1934 over 2,250 slum areas, covering 37,000 houses with 172,000 people, have been condemned. The tendency in England, as in Germany, is toward the construction of small houses on the outskirts of the cities. In England these are going up at the rate of 300,000 a year, over half of which are designed for lower paid wage earners.

France—The French have been pioneers in many phases of child welfare. Her physicians and statesmen have contributed substantially to the advancement of maternal and child hygiene; for example, the organization of crèches (day nurseries), consultations for nurslings (precursors of infant welfare centers), laws for the protection of young children (Loi Roussel), medical inspection of school children, and placing of tuberculous children in country homes (Oeuvre Grancher). Experimental research and practical application in immunization against rabies, diphtheria, and tuberculosis are noteworthy.

The French also have organized sev-

eral national associations for the protection of mothers and children and have sponsored a number of brilliant conferences on child welfare and preventive pediatrics. A new publication devoted to child welfare, *Revue Medico-Sociale de L'Enfance*, was initiated in January, 1933.

Home care with public health nursing is a recent development. More interest is manifested in clinical medicine. In actual organization there has been a strong tendency to institutionalize. Elaborate programs are often laid out, and administration tends to become bureaucratic. A number of brilliant suggestions of the French have been taken up by other nations and adapted successfully to their needs.

We can take lessons from France in her provisions for illegitimate children and their mothers, and in the thoroughgoing manner in which provisions for tuberculous children, both from prophylactic and curative sides, have been carried out. While vaccination against tuberculosis has received a setback in Europe due to the unfortunate Lübeck affair, the French are convinced that BCG is a satisfactory and effective method of immunizing young children against tuberculosis. Over 300 doses of the vaccine were being sent out daily from the Pasteur Institute last summer. Fundamental research was being carried on by Armand-Delille on radiography in childhood tuberculosis, which he has since published in Atlas form. A great impetus to child welfare in France was given during and after the war by American pediatricians and other workers under the American Red Cross and the International Health Board of the Rockefeller Foundation.

Germany—In Germany maternal and child hygiene have been placed upon a scientific basis due largely to the investigations and influence of German pediatricians. Czerny, the greatest of German pediatricians, in his classical

little book, *Der Arzt als Erzieher des Kindes* (The Doctor as an Educator of the Child), indicates the influence which the pediatrician may have in this field of child welfare. A program for the development of local child welfare centers has been adopted throughout the country. Maternity and infant health centers are found in practically all the important cities.

In 1933 there were consultation centers for expectant mothers in 70 cities of more than 50,000 inhabitants; Berlin alone had 46 centers. Maternity benefits were granted in 85 cities last year; the period for which such aid is granted in most cities (63 per cent) is 10 weeks. There are in Germany 922 infant consultation centers, 83 of which are in Berlin. The total number of individual consultations during 1933 was 197,600.

The foundations of this work go back 25 or 30 years and some of its roots to the social insurance plan of Bismarck in 1882. The Kaiserin Augusta Victoria Haus, established at Charlottenburg in 1909, is the parent institution for the training of physicians and children's nurses in child hygiene. Its archives are the most complete in Germany. It has an unbroken history of productive activity of 25 years and is still the most influential institution for this work. Research is continuing, and publications of results appear regularly.

Point XXI of the Nazi program provides that

The state must see to raising the standards of health of the nation by protecting mothers and infants, prohibiting child labor, increasing bodily efficiency by obligatory gymnastics and sports laid down by law, and by extensive support of clubs engaged in bodily development of the young.

There is every evidence that the regime intends to strengthen and extend work for mothers and children. While there have been many changes in personnel in hospitals, clinics, institutes, and wel-

fare organizations in Germany, the structure of its maternity and child hygiene work appears to remain intact. Clinics and health centers are running as usual. Maternity benefits are continued, although on a reduced scale.

Italy—The Fascist State has reorganized completely its maternal and child health program. In December, 1925, it created a new organization, the Opera Nazionale per la Protezione della Maternità e dell'Infanzia (National Institution for the Protection of Motherhood and Infancy). Central headquarters were set up in Rome in 1929 to coördinate closely allied activities in the different ministries of the corporative state and to promote active local coöperation in welfare work for mothers and children through Provincial Federations and Committees of Patrons. The purpose of this institution follows the main lines of development of the Fascist State—a highly centralized, comprehensive, or "totalitarian," organization to bring about unity of methods and action among the diversity of forms of welfare work for mothers and children in Italy. Mussolini has taken a personal interest in this institution as it has to do with eugenics, increase of population, hygienic and social protection of the State.

In order to stamp this national welfare work on behalf of mothers and their little ones with a definite character of its own, the government not only issued regulations, which have been enacted into law, so exact and minute in all particulars as to be termed by the Council of State a complete treatise on the care of mothers and infants, but with significant intention it has devoted the entire revenue from a new tax to supply the necessary funds for the institution; i.e., the tax on bachelors.¹

The program of the institution provides for the collection of statistical data, the organization of a service for the inspection and supervision of institutions, grants-in-aid to institutions most in need of financial help, direct

assistance to mothers and children, antituberculosis prophylaxis, training of specialized staffs for child care, maternal and child health education, reforms of welfare service for foundlings. Maternity and child health centers have been opened in all parts of Italy. Provisions are made to send pre-tuberculous and convalescent children to seaside and mountain resorts.

While there is still a strong tendency to institutionalize and to give clinical treatments, the new institution recognizes the importance of preventive medicine and child care and the responsibility for attention to children in their own homes. There has been improvement of public health nursing since the war, as the result of the establishment of nursing schools on American models shortly after the close of the World War. The recent opening of the new Institute of Hygiene and Public Health in Rome should give added impetus to child welfare work in Italy.

Russia—No account of the provisions for maternal and child welfare in Europe would be complete without mention of the stupendous changes under way for the protection of motherhood and childhood in the Soviet Union. We note the upheaval in thought and action which the Communistic philosophy has wrought in the daily life of women in Russia. Lenin proudly stated,

We have literally razed to the ground all the foul laws regarding the inequality of women, the obstacles to divorce, the odious formalities connected with it, the refusal to recognize children born out of wedlock, and so on, those laws the survival of which are still often to be found in all civilized countries.²

Accordingly, marriage and divorce have been oversimplified, depending entirely upon declaration of purpose. "Illegitimacy" has disappeared both from the Code of Laws and from common parlance.

The rights of children no longer depend upon the form of marriage but

are inherent in blood relationship and in the duty of the state to protect every child and to provide for its education. Both parents are equally responsible for its maintenance, and in case of divorce, alimony can be obtained from the father for its support and education. The mother may declare the paternity of the child even before its birth. The state has taken over very largely the physical and mental care of the child through consultation centers for women and children in connection with obstetrical hospitals and crèches (day nurseries).

The number of cots in crèches in cities and towns increased from 56,921 in 1929 to 365,010 in 1932. A unique feature of the crèche in Russia is its establishment in state and collective farms, and the use of traveling field crèches during harvest seasons. The crèche is taken into the field and the nursing mother at work there can nurse the baby several times a day. The number of cots in permanent crèches on state and collective farms increased from 8,564 in 1929 to 347,617 in 1932, and in temporary crèches on collective farms from 251,400 in 1929 to 4,529,000 in 1932. This enormous expansion has entailed a great deal of readjustment and has made it difficult to secure enough trained workers.

Space forbids the description of extensive work for mothers and children which has been developed in Austria, Hungary, Jugoslavia, Czechoslovakia, and Poland under the inspiration and with the material help of the Health Organization of the League of Nations, American Friends Service Committee, American Red Cross, American Relief Administration, Commonwealth Fund, and International Health Division of the Rockefeller Foundation.

SUMMARY

Lessons we may learn from child health conditions in Europe:

1. The bold experimentation in certain phases of maternal and child welfare now proceeding on a nation-wide basis in many European countries challenges our interest and critical study.

2. An amazing fact in Europe today is the foresight and vigor with which governmental schemes for maternal and child health are being pursued. Whatever the form of government, a desperate struggle is on to preserve, strengthen, and extend essential services for the welfare of mothers and children.

3. The recognition that the first duty of the state is to protect its mothers and children and to provide for their welfare through some form of social insurance is one of the strong points in the European system.

4. In countries where maternity and child hygiene technics have been built upon sound scientific principles and tested over considerable periods they are being preserved with but few pattern changes, regardless of economic, social, or political upheavals.

5. The ability to stick to fundamentals and not become enamored of fads, fancies, and frills, which inevitably break down in times of stress, is a distinguishing feature of child health work in Europe.

6. The stability and continuity of the English system of public health commends itself, because it provides for full-time well trained health officers in every locality, whose position is uninfluenced by political or personal prejudices.

7. There is better control of midwifery in European countries than in America. Adequate facilities are afforded all classes of women for prenatal and obstetric service and for maternity benefits.

8. There is a clear recognition of the intimate relationship between housing and child welfare. Definite steps have been taken by governments abroad to wipe out slum areas and to stimulate the building of sanitary houses for the wage earning classes.

9. The development of health centers as community units of coöperative health work, of generalized public health nursing, and of popular health education as found in the United States has not reached the same high level in most European countries. In these technics the United States has contributed materially to health work abroad.

The Nutritional Aspects of Milk Pasteurization*

E. V. MCCOLLUM, F.A.P.H.A.

Johns Hopkins University, Baltimore, Md.

THE evidences of animal experiment do not show any differences between raw and pasteurized milks.

The actual changes in milk caused by pasteurization are an increase in insoluble calcium of about 6 per cent, a reduction of iodine content by 20 per cent, and considerable destruction of vitamin C. Certain animals have a higher need for calcium than do infants and it may be that raw milk would be better for them than pasteurized milk, but there is no evidence that this is true for children. There is no convincing evidence that raw milk, even if it were safe, is superior to pasteurized milk in infant feeding. Pasteurized milk is probably better since it is more easily digested. The growing practice by pediatricians of boiling milk or of feeding evaporated milk to infants, shows that it is certainly satisfactory. The idea of splitting hairs over slight assumed differences is absurd. We should allow a reasonable margin of safety over the minimum nutritive requirements in child feeding, and this is best accomplished by giving a liberal allowance of milk.

The heating of milk is so great a safety factor in preventing disease that there should no longer be any argument about the superiority of raw milk.

We have an immense amount of clin-

ical evidence gathered from many countries which shows that pasteurized milk has fulfilled the needs for feeding infants and children over many years, with no evidence of damage, provided the loss of vitamin C is made good. The opponents of pasteurized milk have conspicuously failed to make a case against it in favor of the raw product. The marked lessening of incidence of intestinal troubles and contagious diseases carried by raw milk through pasteurization makes it hard to understand how opposition can longer be justified.

It is well known that milk is deficient in iron and in ascorbic acid, and perhaps also in copper, although during pasteurization it probably becomes sufficiently enriched in this element. But we no longer judge a food on the basis of what it lacks. We stress the importance and significance for health of making proper combinations of foods so as to secure effective supplemental effects. No baby intelligently managed is now fed milk alone for any considerable period. It is given cod liver oil and fruit juices early, and supplementary foods as it grows. The problems of feeding normal infants are now satisfactorily solved.

The only recent reports of nutrition experiments which show inferiority of sterilized as compared with pasteurized and raw milk are those of E. C. V. Mattick, and J. Golding, in England, who observed that rats fed biscuit made

*To be read before the Food and Nutrition Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 2, 1934.

of white flour and water, supplemented with milk, either raw or pasteurized, grew normally and reproduced normally, whereas those fed the same biscuit supplemented with sterilized milk failed in reproduction, and of the original rats many failed to reach maturity. Their results seem to differentiate markedly between pasteurized and sterilized milks in their nutritive properties, especially in respect to power to support reproduction.

I have never been much impressed by these experiments for they were not planned in a manner to yield information which could be applied to human experience with diet. It is one thing to demonstrate that a simple mixture of biscuit and sterilized milk is less effective nutritionally than the same mixture with raw milk, and another to translate the condemnation of pasteurized milk used in an entirely different manner in the human diet where it is supplemented with foods more effective as sources of nutriment than white bread biscuit. The fact is that even in these English experiments, pasteurized milk was not shown to have undergone any appreciable deterioration, even when tested in so restricted a manner. No effective supplementary foods were studied in combination with the sterilized milk.

The experience of numerous investigators, including the present writer, and covering many years of studies with animals, shows that pasteurized milk, milk powders and evaporated milks, are essentially the equivalents of raw milk in nutrition. The differences between them is not sufficient to warrant serious consideration. Furthermore, the experience of the pediatric profession with sterilized milk has abundantly demonstrated that excellent results can be secured in infant feeding when such milk is properly supplemented with a fruit juice and cod liver oil and the infant receives supplementary feeding

with appropriate additions as it advances in age. The safety factor afforded by sterilizing milk as a safeguard against infections is so great that there is no question about the wisdom of this system of feeding.

The Lanarkshire, Scotland, study of 10,000 children receiving three-quarters of a pint each daily—5,000 raw, grade A milk and 5,000 pasteurized milk—with 10,000 as controls, gave clear evidence of the beneficial effect of milk feeding on the rate of growth. There was no difference in the raw and pasteurized milks (*J.A.M.A.*, 96:1243, 1931).

Scheunert and Bischoff (*Biochem. Zeitschr.*, 219:186, 1930) studied the food value of raw and heated milk, and found no detectable change in food value. These experiments furnish cogent evidence that cooking (foods other than milk as well as milk) as ordinarily practised, does not interfere with its usual influence on cell metabolism or prevent its utilization for such characteristic demands as growth and reproduction.

In a letter from Lord Dawson of Penn, to the Editor of the *Lancet*, December 13, 1930 (*A.J.P.H.*, 21:389, 1931), he states that pasteurization of milk should be universally recognized.

The Scottish experiment reported here is commented upon by the Editor of the *JOURNAL* (*A.J.P.H.*, 19:415, 1919):

The campaign for the increased use of milk by children and adults is based on sound facts. We still need to push our efforts for clean milk, and we should draw distinction between pasture milk and stall-fed milk, which does not have the same values unless the stall-fed animals are specially dieted.

Fortunately we now have available an excellent study by Leslie C. Frank and others of the U. S. Public Health Service, which should finally silence the critics of pasteurized milk. These

investigators studied children fed raw and heated milk, supplementing the diets ordinarily received by American children in 39 cities and in 10 states. The children to the number of 3,700 were from 10 months to 6 years old. The report states:

The growth-promoting capacity of heated milk plus the supplementary diet received by the average American child of 10 months to 6 years is not measurably less than the growth-promoting capacity of raw milk plus the supplementary diet received by the average American child of 10 months to 6 years.

Analyzing their data they report that there were 32 cases of diphtheria among 1,875 children who received heated milk only, against 40 among the 1,762 children fed predominantly on raw milk, case rates of 17.1 and 22.7 per 1,000 respectively. For scarlet fever, the group fed heated milk showed 43 cases against 73 for the raw milk group, case rates of 23.0 and 41.4 per 1,000 respectively.

Intestinal disturbances reported, such as diarrhea, dysentery, flux, colitis, and summer complaint, amounted to 426 for the heated milk group against 491 for the raw milk group, case rates of 227.0 and 278.0 per 1,000 respectively. When diarrhea was excluded on the assumption that many mild cases were due to causes other than milk, the incidence of intestinal diseases amounted to 208 for the heated milk group against 395 for the raw milk group, case rates of 111.0 and 196.0 per 1,000 respectively. Fifty-nine cases of rickets were diagnosed in the heated milk group against 90 cases in the raw milk group, case rates of 31.5 as against 51.1 per 1,000. The results as they relate to rickets are accounted for by the observation that more of the heated milk-fed children were given cod liver oil than was the case of those fed raw milk. Of the

heated milk-fed children 41.6 per cent were given some cod liver oil as against 27.6 per cent of those fed raw milk. The average weight of the children in the two groups was 33.6 and 33.2 lb. respectively for those fed heated and raw milk. There were no significant differences in the heights of the children of the two groups, *i.e.*, 37.5 and 37.4 respectively. The report shows a significantly higher incidence of diphtheria, scarlet fever, and intestinal disturbances. The report does not consider tuberculosis, but there is strong evidence that this disease has a lower incidence in cities where almost all the milk is pasteurized.

Since the effect of pasteurization on the food value of milk is too slight to be apparent even in specially designed experiments, and is not apparent in observations on children living under ordinary American conditions, there is no valid argument which can be brought forward in support of the marketing of raw milk for the general population. It is granted that certified milk is as safe as any ordinary foods, but if the optimum amount of milk is to be consumed by the public the price must be made as low as is consistent with the maintenance of high quality. The only method of accomplishing this objective, which has the full approval of public health officials and bacteriologists, is pasteurization of the milk supply.

It seems strange indeed that, when we accept so generally the cooking of most of our foods, there should still remain in certain areas a serious objection to the milk heat treatment of milk involved in pasteurization. The menace of bovine tuberculosis to the health of children is so great that universal pasteurization would be imperative if only for the prevention of the spread of this disease alone among children.

Studies in Ventilation

I. Skin Temperature as Related to Atmospheric Temperature and Humidity

EARLE B. PHELPS, F.A.P.H.A., AND ALFHILD VOLD

College of Physicians and Surgeons, Columbia University, New York, N. Y.

IT was desired to secure data on the relation between skin temperature and atmospheric temperature and humidity under ordinary conditions in a steam heated office with window ventilation. In lieu therefore of good experimental control of the extraneous variables, it was necessary to secure a sufficient volume of data to have statistical value.

The skin temperature determinations were made upon three female subjects engaged in routine office activities. Three measurements, one on each cheek and one on the forehead, were made at approximately the same times each day, namely, at the beginning, middle, and toward the end of both morning and afternoon periods. During Period I, March 24 to May 2, 1933, windows were closed for the most part and the office was heated; while during Period II, May 3 to June 30, windows were generally open and there was little use of artificial heat. Wet and dry bulb temperatures and Kata thermometer readings were likewise recorded with each set of measurements of skin temperature.

METHOD OF SKIN TEMPERATURE DETERMINATION

The skin temperatures were measured by means of a thermocouple system designed upon the following considerations. In any metal system in contact with the skin and with the adjacent

cooler air there is a flow of heat and hence a temperature gradient. The equilibrium temperature at any point in the metal is therefore somewhat lower than the true temperature of the surface of the skin, and this deviation constitutes an error in the determination of skin temperature.

This principle and the extent of the error in a typical system is illustrated in the following experimental data. A piece of copper wire, diameter d , was bent to form a right angle, one side of which, the contact arm, 2 cm. in length, was held against the skin, the other, the lead-off arm, L , rising perpendicularly in the air. A junction of fine constantan wire, 0.1 mm., was soldered to the lower side of the contact arm, at its mid-point, so that it pressed upon the skin. A second junction was soldered on the arm L at varying distances, x , above the angle (Table A).

The differences in temperature between the two junctions under various conditions were found to be as shown in Table A.

Accepting these differences as a first approximation to the true error of an actual skin temperature measurement made at point x we note:

1. With a long (5 cm.) lead-off arm, the error increases inversely as the diameter of the wire (I-4, II-3, V-1).
2. The error increases with air movement (I, V).
3. The error increases with the distance from the skin (x) (I-IV).

L = total length of lead-off arm
x = distance, on L, between skin and second junction
* L replaced by 5 ft. silk covered copper wire, 0.07 mm. diameter

4. With constant distance from the skin, the error increases with the length of the lead-off wire (II-III, V).
5. With contact wire of 0.4 mm. diameter and 2 cm. long the error is negligible in still air with the outer junction at the end of the lead-off arm 5 mm. from the skin, and in air at 100 ft. velocity it is 0.1° at 2 mm. from the skin.
6. A lead-off system of silk-covered magnet wire (diameter 0.07 mm.) provides no appreciable cooling of the contact arm.

It remains to be shown to what extent the contact arm itself, at least half the surface of which is exposed to the air, departs from the skin temperature. A sheet of copper 1 cm. thick, placed over the skin, would pass

the normal heat loss with a temperature gradient of about 0.1° between its two sides. Its mean temperature, however, would be determined by the relative thermal conductivities of the skin-copper and the copper-air contacts.

The following experiment gives an indication of the true relation. Two contact pieces were prepared, each 2 cm. long with a constantan junction at its mid-point. They were connected by a fine insulated magnet wire. One piece was pressed onto a piece of filter paper coated with glue, and when dry the paper was trimmed to about twice the width of the wire. The paper in

turn was moistened with glue and coated with a layer of fine asbestos fibre. In this way the upper surface of the wire was partially insulated against the air. This wire was placed on the skin side by side with a similar bare wire. No temperature difference was noted in still air. In air at 100 ft. per minute the protected wire was about 0.05° cooler, during several trials at different spots. The solid insulating material paper, asbestos and glue, with its increased and rough surface was evidently a slightly better heat diffuser than the bare wire alone.

It is evident that a bare copper wire of 0.4 mm. diameter pressed against the skin will assume a temperature very close to the actual skin temperature, even in an air current of 100 ft. per minute, if there be no extension of the wire not in skin contact except a copper

lead-off 0.07 mm. in diameter. We have also noted that wire of this diameter, 0.4 mm. gives a constant reading as between a very light contact or a maximum pressure against the skin, whereas the readings of a heavier wire, 1.4 mm., vary with the pressure.

The results of these studies have been incorporated in a system which is shown in the accompanying sketch (B). The framework is of spring brass wire carrying between the two lower loops a piece of copper wire 0.4 mm. in diameter and about 1 cm. in length which is held to the frame and insulated from it by silk threads. This copper wire constitutes the contact or collecting system.

The junction itself is soldered to this collector at its mid-point and consists of a wire of constantan 0.1 mm. in diameter and one of silk-wrapped cop-

ohms internal resistance, critical damping resistance 200 ohms total, and was balanced to a zero reading by a device which we have modified slightly from sketches kindly shown us by Dr. Swartzchild of the Beth Israel Hospital, New York City, and which have proved of the greatest practical convenience.

In this apparatus, Figure A, a balancing E.M.F. is produced across the resistance R_3 . All variable thermo-electric effects are contained in the high potential circuits, the galvanometer circuit including merely the resistance R_3 ,

of 0.75 ohms, and a damping resistance of 165 ohms, both of manganin. The milli-ammeter has a range of 1.5 m.a. It is calibrated to read directly in degrees by establishing a known temperature difference between the hot junction in an oil bath and cold junction in its thermos bottle, and setting the resistances R_1 and R_2 so that the milli-ammeter reading corresponds to this difference on a scale of $1 \text{ m.a.} = 10^\circ$. Thereafter, R_2 remains fixed and the E.M.F. across R_3 is proportional to the current. Since the thermo-electric

E.M.F. is proportional to the temperature difference, the milli-ammeter calibration should hold over its range. This was actually found to be the case in several thorough calibrations over the range of the instrument. The control resistance R_1 consists of two potentiometers of 1,000 and 100 ohms respectively, giving a coarse and a fine control of the current.

Equilibrium was reached in about 10 seconds after application to the skin, and readings were generally completed after 20 seconds, temperature being recorded to the nearest 0.1° C.

THE DATA

The detailed protocols are voluminous in their original form but can be satisfactorily summarized, as they were for our formal analysis, in the form of three classified correlation tables for each period, which are here presented, Tables I-VI. Skin temperatures, read to 0.1° C., were grouped in 0.5° classes, air temperatures, to 1° F. were grouped in 2° classes, and relative humidities, to 1 per cent were grouped in 5 per cent classes. Tables of this sort were prepared for each of the three

individual subjects as well as for the group. The various characteristics of the distributions and their correlation coefficients are summarized in Tables VII and VIII, in which subscripts s, h, and t refer to the skin temperature, relative humidity and air temperature respectively, the former being expressed in C. degrees, the humidity in per cent of saturation, and the air temperature in F. degrees. M, with appropriate subscript, refers to the mean values, σ to the standard deviations from the mean, $r_{s,t,h}$ to the partial correlation coefficient between skin and air temperature freed from the effect of humidity, $r_{sh,t}$ to the partial correlation coefficient between skin and humidity freed from the effect of temperature and the b's to the corresponding partial coefficients of regression in the final regression equation.

Some individual differences will be noted as would be expected. In the essential details however the values for each period are sufficiently alike to justify treating the combined data as homogeneous and deriving the corresponding analytical equations from them. The standard deviations of the

correlation and regression coefficients given are tests of the validity of the correlations instead of the usual tests of the numerical accuracy; that is, they are computed upon the assumption of zero correlations. In making comparisons in the text the more usual form of the standard deviations are employed.

DISCUSSION

The coefficients of the temperature terms 0.17 and 0.14 respectively with standard deviations of 0.017 and 0.007 respectively, have a difference 0.03 ± 0.02 . We may safely consolidate these two into a single coefficient with a weighted mean value of 0.15. Within the range of these experiments, of ordinary indoor office conditions during the winter, spring, and early summer, the skin temperature of the face varied with the room temperature at a rate of about 0.15° C. per degree F. or 0.27° C. per degree centigrade. Since the difference between skin and air temperature represents the gradient through which the sensible heat component of the total heat loss must pass, and likewise measures approximately the radiation

gradient, this result indicates a decrease in the heat loss by conduction, convection and radiation, and a corresponding increase in the latent heat of evaporation at a rate which in the mean range tends to shift about 3 per cent of the convective loss over to evaporative loss for a change in air temperature of 1° F.

This result is in harmony with the data of Benedict and Root (1926) showing a progressive change in insensible heat loss with changing metabolism and consequent higher skin temperature. We compute approximately from the earlier work of Benedict and Carpenter (1910) that a change in metabolism which would raise the skin temperature 0.15° C. shifts about 1 per cent of the convective loss to latent heat loss. Our results indicate a decidedly greater transfer of the cooling burden to evaporation when the skin temperature is forced upward by increasing air temperature than is the case with increasing metabolism. We note with interest also that if our equation be projected to a room temperature of 37° C., the skin temperature becomes 37° , and the shift to latent heat loss is complete.

$$S = 33.6 + .17(T - 74) + .01(H - 36)$$

Because they touch upon a subject which has been discussed from various angles, theoretical and experimental, and with somewhat varying data and conclusions, the coefficients of the humidity terms are of considerable interest. It is often stated as an accepted fact that evaporation, and the conse-

quent cooling of the body, is lessened with increasing atmospheric humidities. It is true that evaporation from a surface continuously moist, *i.e.*, a free water surface, is a variable quantity depending primarily upon the temperature, relative humidity, and movement of the atmosphere. On the other hand,

if the amount of moisture is limited and controlled by agencies independent of any specified atmospheric property, such as humidity, then the evaporation, and the resultant cooling, are similarly independent.

An example of the first sort is the lining tissue of the respiratory tract; especially the lungs. It will be of interest to determine roughly the influence of variations in atmospheric humidity upon this value. We may take the following hypothetical case.

Lung ventilation	8 liters per minute
Room temperature	20°
Expired air	Saturated at 34° C.

The moisture required to saturate the inspired air, if it be dry, is 38 mg. per liter or 304 mg. per minute. This represents a latent heat of evaporation at 34° of 10.2 Cal. per hour. But if the air be saturated at 20° it will take up 168 mg. per min., equivalent to 5.7 Cal. per hr. The hourly loss of heat by evaporation from the lungs varies therefore at a rate of about 0.045 Cal. for each change of 1 per cent in relative humidity. For a metabolism of 75 Cal. per hour the variation with humidity may therefore be placed at about 0.06 per cent of the total.

If the difference between skin temperature and air temperature represents the gradient through which about 75 per cent of the total heat is passing, a change of 0.06 per cent of the total value would produce a corresponding relative change in the gradient.

The mean skin-air gradient in our series is 10.8° C. Changing this gradient in the ratio of 75 to 75.06 would result in a change of .0086 as against the value of $.01 \pm .004$. In short, the effect of humidity indicated in the formula is readily ascribable to the change in evaporation from the lungs.

Evaporation from the skin is limited

to the output of water. The output is restricted either to a definite quantity, independent of the evaporating conditions of the air; or by having to diffuse through a membrane in which case the evaporation, while not from a free water surface, may nevertheless be similarly dependent upon the drying power of the air.

The testimony of physiologists on this point is varied. Various authorities (e.g. Hancock, Whitehouse and Haldane (1930)), believe that the so-called "insensible perspiration" is chiefly water diffusing by osmosis through the skin and is not the product of the sweat glands. Such diffusion might be accelerated by increased drying on the surface. It would surely cease if the surface became saturated. Vasti (1932) postulates a hydrate compound losing water to the air and absorbing it from the deeper layers.

On the other hand Benedict and Root (1926) show excellent experimental data in support of their thesis that the insensible loss is a definite linear function of the total metabolism over a wide range.

This subject has been satisfactorily discussed by Miura (1931). He states that the consensus of opinion among European physiologists is to the effect that the skin temperature and the sensations of comfort, especially throughout the moderate ranges of humidity found under indoor winter conditions, are essentially independent of the relative humidity. American physiologists on the other hand have tended to follow the suggestions of Houghton, Yaglou and McConnell (1923) of the research laboratories of the ASHVE whose well known chart of effective temperatures assigns a very definite place to relative humidity in the determination of comfort and of the sensation of warmth under indoor winter conditions in the home and office. Miura himself, on the basis of

a most carefully controlled series of experiments, concludes that a difference of 50 per cent in relative humidity results in a change in skin temperature of the face of subjects resting, normally clothed, of approximately 0.25° C. in the same direction, corresponding to a coefficient in the humidity term of our equation of $+0.005$. This is exactly one-half the value which we have found, is somewhat less than the value we estimate as the effect of evaporation from the lungs and, if Miura's results are about the same order of reliability as our own, both series cluster about the computed lung effect within their probable errors.

As a more critical test of the direct relation between skin temperature and atmospheric humidity uncomplicated by secondary reactions and variables we have made a brief series of tests as follows.

A small quantity of air was blown from a 4" funnel upon the forehead at so slight a velocity that it could not be detected unless the forehead was moist. The air was passed alternatively through a can containing calcium chloride or a similar can containing water. Relative humidity varied roughly from 25 per cent on the dry side to 75 per cent on the wet. Temperature was equalized after drying or wetting by passing through a worm in a water tank.

The subject was seated and two thermo-electric junctions, in series, were fastened over his forehead. These were then exposed alternately to the moist and the dry air. The air current alone produced a slight cooling as compared with still air conditions, but in no case among six experimental subjects was there anything more than a temporary drift of the skin temperature when the air supply was changed, and this returned within a minute or two to the initial point. The apparatus and galvanometer used gave readings sensitive to 0.025° .

From various investigations of the water loss, sensible and insensible, from the skin, and also from studies of skin temperature it appears that the important function of skin cooling by evaporation from the forehead and cheeks is, within normal ranges of both temperature and humidity, independent of the relative humidity of the air but that there is a minor secondary effect of relative humidity upon the forehead and cheek temperature due to the varying rate of evaporation from the respiratory tract.

The open air conditions which prevailed during a considerable portion of our second period were evidently largely responsible for masking a similar result in this series. These conditions differ markedly from those in Period I in that the humidity is rather highly correlated with the temperature ($R = 0.51$ as against 0.15 in Period I). The days of higher temperatures and higher humidities were largely days of open window ventilation with increased air movement and consequent relatively lower skin temperatures. In view of the small magnitude of the humidity coefficients in either series and their exact neutralization if the two series be combined it is easier to understand the fairly unanimous conclusion of European physiologists than it is to understand the common acceptance of the view that increased humidity makes for decreased cooling by evaporation.

For the purposes of comparison we consolidate our two equations, eliminating the humidity terms as of no practical significance, and transform air temperature to the centigrade scale, with 20° as standard. This gives

$$S = 32.8 + .27(T - 20)$$

We may now compare our values of the two constants with those from other sources (see next page).

Winslow and Greenburg (1932) recorded 26 sets of observations upon

SUMMARY OF CONSTANTS IN THE EQUATION $S = a + b(T - 20)$

selected spots of the nude body under a wide range of air conditions from which we compute the constants for the nude body. They also show the relation between mean temperatures of the various parts of the body, permitting separate computation for the forehead and cheeks. Bedford and Warner (1934) give the results of 415 observations over a considerable temperature range for bodies normally clothed. Reichenbach and Haymann's (1907) experiments upon 2 subjects have been recomputed in the range 16.5°–28.8°. They also quote a series by Vincent (1890). Ward (1930) has reported a study comparing 81 sets of measurements upon 4 subjects from which we have computed the constants for forehead plus 2 cheek values together. The indicated accuracy is fully justified in view of the careful technic employed.

THE EFFECTIVE TEMPERATURE SCALE

In view of these results and especially of the slight effect of humidity upon the skin temperature, it will be of interest to investigate some of the data from the point of view of the so-called effective temperature in the range in which we are interested. The effective temperature chart is so constructed that a dry bulb temperature of 70° at 50 per cent humidity designates the same effective temperature as a dry bulb of 75° at zero humidity. In this region, therefore, if skin temperature is to follow

effective temperature, the humidity coefficient must be one-tenth of the temperature coefficient in equations of the type of those we have used. This would allow about 50 per cent greater influence to humidity than is indicated in our first period equation, about twice as great an influence as we compute from the lung evaporation alone and about three times the value found by Miura (1931), a point which the latter noted. All these values however are well within the probable errors of data compiled from a short series of studies. In Winslow and Greenburg's (1932) series of 26 observations, for example, we compute a humidity coefficient of $+0.02 \pm .04$. It is not surprising therefore that when any given series of skin temperature data are correlated with air temperature it makes little difference whether the humidity factor is included, as effective temperature, or excluded. We have computed such correlation coefficients using the data of our two periods separately and have also made a similar computation with the data of Winslow and Greenburg (1932), which they plot to show an excellent linear relation with effective temperature. Results by the two methods of computation are identical (p. 970).

SUMMARY AND CONCLUSIONS

Skin temperatures of the cheeks and forehead were determined upon 3 female subjects engaged in office work

CORRELATION COEFFICIENT r

Skin Temperature Against

	Air Temperature	Effective Temperature	S.D.
Present Study

Winslow and Greenburg	.93	.92	.03

in a steam-heated, window ventilated office during the winter, spring, and early summer of 1933. Readings were made five or six times a day together with wet and dry bulb temperature reading in the office.

A statistical analysis of the data indicates:

1. A positive correlation between skin temperature and room humidity during the closed window seasons which is wholly ascribable to evaporation from the respiratory tract and which is so small as to be readily reversed by the slight effect of freer ventilation in the open window season.

2. A positive correlation with air temperature, indicating a rise in skin temperature of 0.14°C . per degree F. in room temperature (0.27°C . per degree centigrade) and a corresponding shift of 3 per cent of the total heat loss from radiation and convection to latent heat of evaporation. Similar coefficients, reported by or computed from the work of other investigators are shown for comparison.

3. The effective temperature scale, while admirably suited to comparisons in the higher temperature range of industrial conditions overestimates the relation of humidity to skin temperature in the range of ordinary office conditions in the winter.

Finally it remains to be pointed out that the sense of comfort as expressed in "comfort votes" and as felt by the individual, is largely determined, and can be objectively measured, by the skin temperature, possibly with the aid of some measure of the internal gradients as suggested by Bazett and McGlone (1927). The latter factor is clearly in evidence during rapid readjustment to changed conditions, but under equilibrium conditions we find Ward's (1930) data especially significant. The

comfort votes of 4 individuals were correlated with forehead temperature by coefficients (r) of from .80 to .96, or for the group .88.

In the further search for those evasive combinations of environmental characteristics, which are found to make for a sense of comfort, we believe that progress depends upon recognition of the fact that the body comes fairly quickly into quantitative thermal equilibrium with any environment that is not too extreme, but that large and significant shifts in the qualitative manner of heat loss are often brought about by apparently minor changes in the environment.

It follows therefore that the "cooling power" of the air as indicated by charts of "equivalent" conditions, or by any of the various instruments which integrate the effects of two or more air properties, is not a criterion of that qualitative distribution of the manner of cooling which alone, rather than the fairly constant total rate of cooling, appears to affect comfort.

Storage Battery Plants, New York State, 1933

J. D. HACKETT

Prepared by Division of Industrial Hygiene, New York State Department of Labor, Albany, N. Y.

FOR the past several years an effort has been made to record the incidence of sickness due to lead poisoning on a *rate* basis. The object of this is to compare the rates of one factory with another, of one year with another, and the collective rate with that of others outside of state. The results for 1933 are now on record and, as will be seen by the table, there is a slight improvement over 1932.

There is a lead poisoning frequency rate of 9.25 as compared with 10.56, and a severity rate of 0.52 as compared with 0.58 for 1932. These figures, representing average practice, divide the factories of the state into two classes, those above and those below average. Hence, those needing to take additional preventive measures are indicated clearly.

The small plants have a distinctly high rate and it is certain that the figures indicate that preventive measures if adopted are not thoroughly effective.

The figures submitted indicate the minimum incidence of lead poisoning;

there may be unsuspected, unreported, or inconclusive cases, since the facts are obtained by correspondence and not by an independent investigator. For instance, in one case a claim is made for death due to lead poisoning on behalf of a deceased worker and this is denied by the employer. The case, being still in dispute, no figures appear. This indicates a limitation in the use of severity rates applied to occupational poisons, since the time lost may not be included in the period in which it occurs. But a subsequent correction is possible.

Although New York State as a whole shows an improvement, its figures compare very unfavorably with those of lead battery manufacturers outside the state. Certain plants outside the state, working more than twice the time, have one-third of the hours lost and a considerably lower relative frequency and severity rate. These figures indicate a high standard of hygiene practice and the need for more vigorous measures of prevention against lead poisoning in the various plants of New York State.

LEAD POISONING—STORAGE BATTERY FACTORIES

	<i>New York</i>		<i>Outside the State</i>
	1932	1933	1933
Total man hours worked	852,950	1,188,281	2,579,672
Total hours lost due to lead poisoning	4,936	5,647	1,864
Total number of cases		11	5
Frequency rate	10.56	9.25	1.94
Severity rate	0.58	0.52	0.09

DENTAL CARIES¹

SOME of the most common ills to which man is heir are the least understood and the most refractory to control. The outstanding instances are the common cold and dental caries. In spite of the fact that large sums of money have been spent on research, and that capable clinicians, laboratory workers, and dietitians have been studying dental caries for years, it must be said that we are far from knowing its cause, and this means that we do not know the prevention. In spite of tooth brush drills, lectures on cleanliness, and cocksure statements that a clean tooth never decays, caries still afflicts the great majority of people.

While no one would advocate deliberately putting children on deficiency diets with the object of producing caries, we have in the various strata of our society many thousands of cases in which diets are deficient and which have furnished some evidence, though there is no record of just what many of these people have eaten or for how long. The majority of experiments have been carried out on dogs and rats, neither of which have teeth comparable in shape or arrangement to those of man. It is also evident that many of those writing on the subject have had inadequate knowledge as well as poor laboratory facilities, and many alleged experiments have not been continued for a sufficient length of time to be of value.

Some regard susceptibility to caries as being due to causes lying within the tooth itself, considering that the bacteria of the mouth and other local factors are of minor importance as compared with a well balanced diet. Some hold that balanced diets act in the prevention of caries by improving the general resistance of the body tissues. Others hold that the teeth are akin to bone in many respects and that prevention of caries may be attained by measures which insure the normal metabolism of calcium and phosphorus, one observer even assuming the existence of dental lymph circulation which concentrates, then carries, the acid-neutralizing properties of the blood to the surface of the enamel. Still others

believe that maintenance of the normal concentrations of phosphorus in the blood is the goal to be aimed at. Adequate supplies of vitamins A, C, and D have all been considered important in the development of teeth and the maintenance of their health. One of the most recent pieces of work indicates that vitamin D is the "most important single corrective factor."

Apart from actual injury by mechanical means, most students believe that tooth decay is brought about by action of acid formed by fermentation of carbohydrates on the enamel, leading to exposure of the underlying structures. This idea was advocated at least as far back as 1840, and there are many strong supporters of it today. At the School of Dentistry of the University of Michigan, Hadley and Bunting, after a prolonged series of studies running as high as $1\frac{1}{2}$ years, advocate this view and believe that the chief organism in bringing this about is the *Bacillus acidophilus*, which has the power of fermenting carbohydrates and can live in concentrations of acid of a pH as low as 3.2. In England, Sim Wallace is the chief advocate of carbohydrate fermentation as a cause of caries, though he has not so far identified any particular germ with the process.

The studies of Hadley and Bunting show that in persons with active tooth decay, the *B. acidophilus* is usually present, and that the numbers of these organisms in the saliva are directly related to the degree of susceptibility of the individual. They have studied groups which they classify as "immunes," "caries-inactive," "developing inactivity," "developing activity," and "constant activity," for periods lasting from 27 days to $1\frac{1}{2}$ years, and hold that there is a distinct relation between the number of *B. acidophilus* present per c.c. of saliva and the activity of caries. Occasionally positive results were obtained on salivas from "immunes" and "caries-inactive" persons, and negative results from susceptibles and those developing susceptibility. "The general bacteriological picture, however, is radically different, both qualitatively and quantitatively, for those representing the above noted extremes in caries activity." Their experience has satisfied them that in 85 per cent or more of the cases studied, the clinical findings are correlated very closely with the bacteriological picture. They have demonstrated that caries was produced in children on diets generally recognized as satisfactory for growth and well-being. Not only were careful records of the daily food intake kept, but analyses of the blood serum, studies of calcium and phosphorus retention, and medical observations all indicated that the metabolic processes were normal. Their appetites remained good, gains in height and weight and general behavior showed them to be normal.

There are a number of studies which indicate that the physical consistency of the foods is of greater importance in producing caries than the chemical composition. When rats were fed rice or corn coarsely ground, no caries resulted, but when mixed with the finer portions, caries resulted invariably. Bunting feels sure that the feeding of sweets, providing an extra caloric intake, is often the determining factor in producing caries in children on adequate diets. In an orphanage with inmates running from 6 to 18 years of age and in which the diet had been definitely deficient for 6 or 7 years, caries was inactive in 57.1 per cent of 49 children over a period of $2\frac{1}{2}$ to $4\frac{1}{2}$ years, and in 71.5 per cent of 109 children over a period of $1\frac{1}{2}$ years. The great majority had cavities on admission and 40 per cent were deficient in height, according to Woodbury standards. The explanation of the improved condition as regards caries is held by Bunting to be in the very low intake of sweetened food as well as the uniformity and regularity

in meals. Forty to 45 per cent of the calories received by these children was derived from starch, mostly cereals.

Bunting and his coworkers acknowledge freely that many observations do not lend themselves to ready explanation and doubt if there is any single principle which can be applied equally to all persons. Some are immune, and for these people it makes little difference what they eat. Possibly this immunity lies to some extent in the inability of the *B. acidophilus* to thrive in their bodies, and this is probably hereditary. There are others who are so susceptible that no diet can check the disease. For the great majority of people who are moderately susceptible, a great measure of protection is afforded by diets which are low in artificial sweets.

There are almost as many opinions on the causation and prevention of caries as there are workers on the subject.

OPHTHALMIA NEONATORUM

PERHAPS the great majority of us feel that ophthalmia neonatorum has been conquered. From the scientific point of view, this is true, but from the practical point it is not. In spite of the studies which led to the prophylactic treatment by Credé in 1881, ophthalmia neonatorum is still too common. His method was the introduction of 2 per cent solution of silver nitrate into the conjunctival sac at birth. The fall in the incidence of the disease wherever this was done was striking. In Berlin it is said to have fallen from 9.14 per cent to 0.9 in one year in the maternity hospitals. In Munich the incidence fell from 10 per cent to 0.9. On April 1, 1914, in England and Wales, the disease became compulsorily notifiable, and following this, hospitalization was urged, the first special ward for such babies and their mothers having been instituted in Liverpool in 1907.

In 1918, the London County Council set apart St. Margaret's Hospital for a similar purpose. The Public Health Regulations in England define the disease as "a purulent discharge from the eyes of an infant, commencing within 21 days from the date of its birth." Results in other countries bear out those mentioned. Treatment was made compulsory in Denmark in 1900, it being required that 1.5 per cent solution of silver nitrate be instilled into the eyes of every child at birth. In that country the incidence of the disease dropped so that in 1925 they had only one case every second year.

Compulsory notification and treatment probably increases the number of alleged cases and makes statistics somewhat unreliable. On the other hand, the saving of eyes of affected children more than balances such mistakes. For example, in Edinburgh, in 1930, in a series of 173 cases the only accident was impairment of vision in one eye in one child, due to a delay of 10 days in sending the child to the hospital. In the same city during a 12 year period, 393 cases were reported and 202 were treated in hospitals, and in the 12 year period covered, impairment of vision has resulted only in the one case mentioned.

The best practice seems to begin with the mother in prenatal treatment. Accurate diagnosis and efficient treatment of every case of vaginal discharge must be carried out, and if the male parent is affected with gonorrhea, the treatment should extend to him also. The prophylaxis at birth consists of thorough cleansing

of the maternal organs and the instillation into the eyes of children of some antiseptic.

Curiously enough, there is controversy over what this antiseptic should be. Perhaps the majority of people are inclined to use silver nitrate, but there is high authority against this, since the 2 per cent solution of nitrate of silver may lead to "silver catarrh" and some opacity of the cornea. In the United States, de Schweinitz believes that it is not always advisable to use as strong a solution as 2 per cent, and holds that even the 1 per cent solution should be confined to suspected cases. It should be applied only by midwives who have had proper training or by doctors. Other silver preparations, notably the acetate of silver in 1 per cent solution, or some of the organic silvers, such as argyrol in 20 per cent solution, are recommended by some. Some authorities maintain that proper cleansing of the eyes at birth is more important than the silver salt, and advise that the eye should never be opened until the entire face has been thoroughly cleansed—especially the skin of the upper and lower eyelids. Other authorities are just as insistent in warning against the use of substitutes for nitrate of silver, and all prophylactics except silver nitrate are condemned.

It goes without saying that the preparations of silver should be reasonably fresh and in good condition. Practically all authorities agree in advising that the nitrate of silver be neutralized with normal salt solution to prevent its action from continuing for too long a time. In England there seems to be a strong opinion that the facilities for teaching medical students as well as midwives are deficient. The Council of British Ophthalmologists in 1928 pointed out that the instruction of midwives was poor and that most of the instruction was theoretical. In their opinion, practical experience should be provided during the course.

We cannot but conclude that ophthalmia neonatorum and the large toll of blindness which follows are comparatively easy to prevent. The principles were laid down more than 50 years ago, and have never been controverted. Indeed, experience everywhere has shown the soundness of Credé's original teaching, and no marked modification has been introduced which can be regarded as a distinct advance.

REPRINTS ON HIGH-TEMPERATURE, SHORT-TIME PASTEURIZATION AVAILABLE

AT the request of the Laboratory Methods Committee of the International Association of Milk Dealers, a review of scientific information on the subject of "High-Temperature, Short-Time Holding Pasteurization in the United States" was prepared in 1933 by Dr. M. W. Yale of the New York Agricultural Experiment Station, Geneva, New York. This work was published in the *Proceedings of the 26th Annual Convention of the International Association of Milk Dealers* for the Laboratory Section. It also appeared in the March and April numbers of *The*

Milk Plant Monthly for the year 1934.

Modern types of high-temperature, short-time pasteurizers in use in this country for the treatment of market milk supplies are illustrated and described. The paper deals mainly with studies of health authorities and others on cream layer volume, flavor, bacterial reduction, development of thermophilic bacteria, and tests with pathogenic bacteria.

Reprints of this work are available and may be secured upon application to the New York State Agricultural Experiment Station, Geneva, N. Y.

LETTER FROM GREAT BRITAIN

TWENTY-ONE YEARS' EXPERIENCE OF TUBERCULOSIS SCHEMES

The conferences of the National Association for the Prevention of Tuberculosis are held alternately in London and in some provincial center. This year provided an opportunity for the metropolis to welcome the conference, and since it was something of an occasion, being the year of the attainment of the majority by tuberculosis schemes in this country, no less, it was appropriate that London should be the meeting place. The attendance was smaller, perhaps, than the occasion demanded and had been expected, but what the meeting lacked in numbers it made up in distinction and enthusiasm. Being a meeting historically important, not unnaturally there was a great deal of "then and now" talk, and of congratulatory reference to progress made.

Prominent among those making addresses was Viscount Astor, who has long been interested in the tuberculosis problem, having been, in fact, chairman of a special committee set up in 1912 to consider it and to offer suggestions with regard to methods of dealing with it. Many of the elements later incorporated in the tuberculosis schemes of health authorities were, in fact, suggested by the Astor Committee. Generally, Lord Astor is recognized as one responsible for much of the really considerable progress made toward the solution of the problem and the reduction in the mortality from pulmonary tuberculosis from 1.08 per 1,000 in 1911 to 0.69 in 1933: and the fall in deaths from other forms of tuberculosis to 5,405 in 1933 from 13,888 in 1911.

On this occasion, Lord Astor was particularly concerned with the question of the relation of the milk supply to

tuberculosis, and the necessity for tuberculin testing of cows with tuberculin of a uniform standard. The subject set down for discussion by the conference was "The National Tuberculosis Scheme: The Experience of Twenty-one Years." More or less, the discussion centered round what were, when the scheme was established and no doubt still are, the two main elements—the dispensary and the residential institution. In regard to each a great deal that was said had reference to administrative rather than purely medical matters. Not only to the openers—Dr. Lissant Cox of Lancashire and Dr. Melville Dunlop of Edinburgh—but to subsequent speakers, the principal defect seemed to be a tendency for the dispensary and those associated with it to work in a watertight compartment. The need, therefore, was for closer coöperation between the dispensary and other activities of the health department in the schools and institutions, for example.

Speakers in the discussion on residential institutions sought to show that most astonishing and revolutionary changes had taken place. The old-fashioned sanatorium, it seems, has completely disappeared, replaced by a hospital very largely surgical in design, presided over by a physician who is less an authority on tuberculosis than a hospital director. The conference in general was a very pleasant and interesting one and, if it did no more, showed at any rate the extent of the progress made in the twenty-one years during which schemes have been in operation; how matters now stand, and the directions which effort in future should take.

PREVENTION OF CHILD TUBERCULOSIS

At the National Conference on

Maternity and Child Welfare, which was held at Birmingham some two or three weeks after the Tuberculosis Conference, among other matters tuberculosis again came up for review.

In a paper on the prevention of the disease in children under 5 years of age, Dr. Dixon, the tuberculosis officer of Birmingham, opened a discussion that interested the conference greatly. From figures submitted, which proved that some 20 per cent of 1,813 cases investigated gave a history of contact in the home with a known case of pulmonary tuberculosis, it seemed clear that preventive action of some sort was necessary. The lines suggested were the production of some degree of immunity, and secondly the introduction of measures that will result in breaking the child's contact with a known source of infection. In the latter connection reference to the need for coöperation between the infant and school child welfare workers and those engaged in tuberculosis work was made.

Segregation of infective cases was also praised as advantageous, though it is interesting to note that the voluntary was counted preferable to the rigorous and compulsory isolation of cases, since in many instances the latter might be a harsh procedure.

A note in this paper worth repeating has reference to the fact that in the colonies at Papworth and Preston Hall, no child born in the village has yet shown evidence of clinical tuberculosis, and no single case of tuberculous meningitis in a child has yet occurred. "Moreover," it is added, "the children, when old enough to work, enter the workshops in the colony and work in daily contact with tuberculous persons."

Among other subjects of importance discussed at this conference were the reduction of neonatal mortality and orthopedic work among preschool children, the contributors including Dr. G. F. McCleary, who, though he is

better known as an authority on matters connected with the operation of the national insurance acts, has made some notable contributions on the subject of infant welfare.

AMERICAN DELEGATES TO THE HEALTH CONGRESS

The Health Congress of the Royal Sanitary Institute, generally regarded and accepted as the one occasion during the year when workers in, and persons concerned with, public health and preventive medicine can meet and confer together, was held at Bristol from July 9 to 14. If it was no more, it was certainly no less brilliant as an affair than any of its predecessors. If anything it had more of an international aspect than usual, visitors from other countries and British dominions overseas attending in considerable numbers. Prominent among these were Professor Walter Brown, who, in responding to the toast of "The Guests" at the "overseas luncheon," one of the pleasantest of the functions held during the week, appeared to share the astonishment at being grouped with foreigners in my country that I have experienced at being similarly classed in his!

Other colleagues from the United States it was a great pleasure to meet and greet were Passed Assistant Surgeon R. B. Holt, representing the Government, and Dr. Jackson Davis, who, with Professor Brown, represented the Association and at the same time acted as delegates of the New York State Department of Health.

Thomas B. Appleget and Dr. G. K. Strode of the Rockefeller Foundation, the latter its representative in Europe though not included in the official list of delegates, spent several days at the Congress and were very welcome visitors. Dr. Holt and Dr. Strode both took part in discussions, and the former, in addition, made an attractive speech at the opening ceremony.

The programs of the various meetings were very heavy, but in spite of the exceptional warmth and fineness of the weather, the great bulk of the 1,500 persons present appeared ready to attend and to take part in discussions. The attendances at the numerous social functions were very large also, perhaps all the larger because the climatic conditions were so favorable. This was particularly the case with outdoor functions such as garden parties, several of which had been arranged by the authorities of the University of Bristol among other of the several very hospitable bodies and individuals in the city.

One of the most interesting hosts was the Society of Merchant Venturers, which dates back to the 14th century and claims Cabot as one of the earliest of its chairmen. Possibly for this reason the society is extremely exclusive, and invitations to such functions as the luncheon given on the occasion of the congress are greatly valued by the recipients.

STERILIZATION OF MENTAL DEFECTIVES

Of the subjects discussed at the sectional meetings and conferences, many naturally had what was practically a local appeal only, having reference to difficulties and details, administrative mainly, with which health workers in this country are faced.

In a number of places quite a considerable amount of attention was given to the subject of housing, with which, as I have already explained, strenuous efforts are now being made to deal. Just how serious these efforts are may

be judged from the fact that the Minister of Health himself (Sir E. Hilton Young) considered it worth while to attend the congress for the purpose of delivering an address.

In more than one section also the discussions had reference to the question of mental hygiene. This was particularly the case in the Preventive Medicine Section where a session jointly with the Conference of Medical Officers of Health was devoted to a consideration of the problem of the mental defective. In this I was particularly impressed by the number of references to such procedures as euthanasia and sterilization as remedies. Coming from specialists in the treatment of mental diseases, several of whom attended and spoke, I was interested in the criticisms made of the recommendations in favor of voluntary sterilization offered by the departmental committee set up by the Government to consider the question. Considerable doubts were expressed as to the likelihood of any effect whatever upon the problem being produced by the procedure. If it was to be adopted at all, the view seemed to be that it was preferable that it should be voluntary, the experience of Germany, where drastic measures had resulted in the concealment of cases of defect, being unfavorable to the adoption of anything resembling compulsion. Among contributors to this discussion were Dr. Holt and Dr. Strode, the joint presidents of the section and conference being two Honorary Fellows of the American Public Health Association, Professor W. W. Jameson and myself.

London CHARLES PORTER, M.D.

PUBLIC HEALTH EDUCATION*

"There are no dull subjects; there are only dull writers."

Mobilization for Human Needs—

The health agencies supported, at least in part, by community chests will be much concerned with the plans for the intensive mobilization period, Oct. 21 to Nov. 11, 1934.

Much national publicity is to be issued by Community Chests and Councils, Inc., 420 Lexington Ave., New York, N. Y.

Health workers may contribute to the success of the nation-wide effort by supplying ideas, statistics, and other factual material including case stories. Most useful will be anything showing needs or results, or progress in terms of results.

Send such material to Louise Franklin Bache at the above address. Miss Bache is the author of *Health Education in an American City*.

An Exhibit of Mail Campaigns—

The Direct Mail Advertising Association announces that it will build a new traveling display showing how major industries use direct mail. There will be a social service section, which would include health. Users of direct mail for money raising or otherwise, are invited to submit specimens to the Educational Committee, Elmer S. Lipsett, chairman, 89 Broad St., Boston, Mass.

Paintings Show Hospital Life—

Under the title, "Hospital Art Shown at World's Fair," the *Trained Nurse and Hospital Review* for July, 1934, describes a series of 40 paintings by Kay Bishop, which are now hanging in the Hall of Science. Six of the pictures are reproduced. Whatever is to be done with them when the fair closes, it seems probable that these paintings will serve a useful purpose for a long time to come, both in the original and for reproduction. (468-4th Ave., New York, N. Y. 35 cents.)

Scientific Information and Newspaper Readers—

Austin H. Clark, biologist and member of the staff of Smithsonian Institute, has for several years directed press service for the American Association for the Advancement of Science. Out of this experience he tells scientific men some of the problems in adapting scientific material to newspaper readers. Of special interest to health workers is his statement that

Articles concerning the physical and mathematical sciences must be written more or less on a witchcraft basis.

Urbanization and the phenomenal engineering and mechanical advances of the past quarter-century have so isolated us from the fundamental factors of our natural environment that we are prone to regard ourselves as wholly free from the mental shackles of superstitions and the belief in the supernatural that characterize men and women

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

less fortunately situated—that is to say, savages and our own ancestors.

But, while continuing to flatter ourselves with this comfortable belief, let us constantly remember that the human mind has not changed, and that all the beliefs we deprecate in the so-called savages and try to forget in relation to our own forbears exist today in most newspaper readers—and also in us—in a more or less modified form.

Successful publicity for science is based first of all upon the recognition of people for what they are; it is futile to assume that we can make them over into what we would like them to be.

He also stresses the fact that the public is interested in personalities and emotions, while scientific men believe at least that they appreciate the world on the basis of determined facts. Every scientific article written for popular consumption, he says, must be tied to some personality. And “in addition to being tied to some personality it must have as a keynote—love, hate, gain, loss, mystery, or some other basic emotional concept.”—*Editor and Publisher*, Times Bldg., New York, N. Y. June 30, 1934. 10 cents.

Not Talking Down, but Talking With Readers—The *New York Daily News* has in its 15 years built an enormous circulation. In the discussion of its policies in *Editor and Publisher*, June 30, its general manager takes issue with a criticism that it is edited for 14-year-olds. The intelligent adult, he says,

... revels in a display of brawn and mastery. That is human nature. Perhaps the same man will come home from the prize fight and pick up Shakespeare and read it and enjoy it. It is our feeling that the 14-year-old mind, and even the 8-year-old mind, is a part of the mental equipment of the average human being.

He adds that the *News* is edited to meet the various requirements of the average person's mental equipment. He thinks that it is of greatest importance that its writers should be a part of the

crowd. They should feel as the masses feel and like the same things that the masses like. (Times Bldg., New York, N. Y. 10 cents.)

Some Approaches to Broadcasting—Before us are three series of weekly or twice a week radio talks sponsored by city and state health departments. They cover periods of about 6 months. Back of each of these three broadcasting programs was a conception of the task, or at least, a state of mind about it that is worth considering as you review your own recent programs or your plans for the coming year. The first series might be described as an “its your turn now” technic. Evidently the head of each bureau in the health department was assigned his or her period on the air, given the allotted number of words. From this point on, there is no evidence of any plan or supervision. Half of the talks seem quite unsuited to radio—prepared as though to be delivered in a classroom. The others are more or less interesting, but on widely varying intellectual levels. There was nothing in the series to attract or hold a steady group of listeners. Whoever was responsible for the series regarded his part in it as merely one of arranging dates and getting copies of the talks into circulation.

The second series was also passed around among bureau heads, and also other health specialists, but someone with a pretty definite idea as to what radio audiences would like must have consulted, revised, coached, titled, and otherwise kept the whole program on a level with the interests of everyday conduct the talks were intended to influence. Both titles and opening paragraphs suggest familiar experiences, or use familiar phrases.

The third is a one-man series and apparently the speaker was chosen because he could do this kind of thing

better than anyone else. The talks appear to be planned for a somewhat limited audience, made up of those who want to be better informed rather than those who are looking for advice for immediate use; but certainly the radio supplies such an audience. There is an appeal to the intelligence, but no strain on the capacity for sustained interest. Historical information and anecdotes are used to introduce talks on medical discoveries and the conquest of disease.

Telling the Public About Maternal Mortality — The obstetric advisory committee of the Children's Bureau urges that "there should be widespread education of the public as to the *ing*":

1. That the high maternal death rate is due largely to controllable causes.
2. That it is necessary for all women to have adequate supervision and medical care during pregnancy, labor, and the postpartum period, such supervision and care to begin early in pregnancy and to be continuous through the postpartum period—
 - a. In order to safeguard the health of both mother and child.
 - b. In order especially to control the infections, toxemias, and hemorrhages that this study and others have shown to be real menaces to life.
3. That there is danger of death or serious invalidism following abortions, spontaneous or induced.
4. That the community has a definite responsibility to provide adequate medical and nursing facilities for the care of women during pregnancy, labor, and the postpartum period. This predicates the proper organization of hospitals, outpatient services, and medical and nursing personnel, and applies to both home and hospital care. The community should know the standards for hospitals taking obstetric cases that have been drawn up by the American College of Surgeons.
5. That judicious selection of the hospital to be used for maternity care is of the greatest importance when hospitalization is planned.
6. That the better education of those caring for women during this period is essential and should have public support. This in-

cludes adequate obstetric training for medical students, postgraduate obstetric training for physicians in practice, to keep them abreast of modern developments, the training of nurses in good maternity care, and the training and supervision of midwives in communities where midwives still practise.

7. That it is important to make careful and intelligent selection of the attendant for maternal care.

Physicians should assume leadership in a number of directions, including:

1. Informing the public that the high mortality during pregnancy, delivery, and the postpartum period is due largely to controllable causes.
2. Warning the public as to the dangers occasioned by abortions, spontaneous or induced.

From *Maternal Mortality in Fifteen States*, a study of the Children's Bureau. Superintendent of Documents, Washington, D. C. 234 pp. 20 cents.

Getting a Thrill Out of Figures—There is no attitude of "take them or leave them" about the service statistics in the Palama Settlement's 1933 report. They are all told as though figures were exciting.

35,701 hours of public health nursing represent another phase of Palama's contribution to the community.

Think of 35,701 hours packed with highly skilled ministrations to the sick, persuasive health teaching to the well, supervision of the health of the children in 22 public schools and 14 kindergartens.

Think of 591 women carried through many months of pregnancy with health guidance under medical supervision in 154 prenatal conferences and with *no deaths from maternal causes*.

Think of 1,610 infants under 1 year of age and 1,534 between 1 and 6 years of age receiving, in 579 child health conferences with physicians and nurses, health guidance that a few years ago no amount of money could buy.

This is an exceptionally interesting and attractive report of work at a health center. Philip S. Platt, Director, Palama Settlement, Honolulu, Hawaii.

A 40-year-old Book Still Going Strong—"Publication today of the fifteenth edition of a work of non-fiction that has been read more widely by women than any other published in America prompts the First Reader to consider this unique phenomenon in the manner of the author":

What book has this remarkable distinction? It is Dr. L. Emmett Holt's *The Care and Feeding of Children*.

How do you account for that?

It has sold 800,000 copies, and every copy has been read by at least 5 mothers and discussed by 20. It is known as the "Baby Bible," and a whole generation has been brought up on it.

How did it get this extraordinary distinction?

Because Dr. Holt put aside the pretensions of the medical priesthood and in the simplest terms discussed the care of children so that every mother could understand it. Besides, he wrote advice that was meant to keep the child well. He did not alarm the mother with a parade of symptoms and a list of preposterous precautions. He did not tell anecdotes of all the terrible cases he has observed as a physician. He took for granted that the young mother wanted to know how to feed, clothe and train her infant and keep him healthy and gaining. And because he had a fund of simple words he put it into the English language, forgetting Latin, Greek, and the passwords of the doctors.—Harry Hansen in *New York World-Telegram*, July 19, 1934.

Dollars or Children?—The puzzling combination of falling death rates and a widespread hunger is the theme of an article by Paul De Kruif called "Dollars or Children" in *Ladies' Home Journal* for August, 1934. The author refuses to accept "the blessings of poverty" point of view in the face of mortality statistics which seem to give validity to that phrase. "I have just begun to understand how the science, the brains, the wit, the devotion of a miserably paid small army of men and women can guard a fundamentally teachable mass of humanity from the deadliness of this needless poverty. It is a gleam of hope in a world gone

hay-wire, this spread of knowledge down to the lowest depths, trickling an economic system that puts dollars ahead of the lives of children." He tells the story of Detroit's public health education work and coöperation of physicians declaring that it is only because brains and devotion with next to no money are still there, that sickness is prevented.

I wonder if we hadn't better urge our searchers to turn from their marvelous death-preventing diphtheria toxoids, to look for a real cheap vaccine against the spiritual miasma that's beginning to follow want amidst plenty? There was a very crabbed old Scotsman, Thomas Carlyle, who understood it when he said: "It is not to die, or even die of hunger, that makes a man wretched; many men have died; all men must die—the last exit of us all is in a fiery chariot of pain. But it is to live miserable we know not why; to work sore and yet gain nothing; to be heart-worn, weary, yet isolated . . . girt in with a cold universal *laissez faire*."

I'm beginning to look a little into the happiness of these children in my state of Michigan. Happiness is built fundamentally on vitality. And if the children's vitality is only maintained—why should we be so proud that in spite of needless want we've simply maintained it?

Environment can lift the vitality and happiness of children. Except for those queer dollars, environment is here as we choose to make it . . .

This article, by the author of *The Microbe Hunters*, is a contribution to public understanding and appreciation of health work for which both health officers and privately supported health agencies may well be grateful.

A Review of a Two-year Radio Program—Mimeographed copies of the radio talks on personal and public health presented by the Jefferson County Board of Health, Birmingham, Ala., during the last two years have been bound together in two convenient reference volumes under the title, "Health by Radio." Since a regular program of this kind reaches a fairly stable nucleus of listeners, it may be considered as a whole as a teaching

program. From this standpoint, a good feature is the repetition from time to time of the same subject under different titles, and as part of more inclusive talks. For example, tuberculosis is the theme of at least four separate broadcasts in Volume II, and is brought up again and again in connection with broader topics.

A broadcast on "Medical Words and Their Meaning," seems to us a topic worth repeating more than once. Too many words were defined in a single talk. This important factor in broadcasting, of getting technical terms understood, might well take account of the difficulty in grasping unfamiliar words when they are heard and not seen. Words like bacilli, antitoxic, micro-organism, miasmata, were used in the process of defining other words, thus piling up the listener's confusion rather than helping him out of it. The advertiser repeats the name of the product over and over again and spells it more than once.

Perhaps the announcer made up for the rapidity with which words and ideas were passed over by urging people to send for the talk. A reminder that you could get a copy of the talk could be given in the course of the talk as well as at the beginning and the end.

The occasional use of provocative titles in addition to the simple descriptive titles like "Nerves," "Sleep," and "Summer Colds," is a good feature. "The Disgrace of Dying" is a novel way of arousing a sense of responsibility for both personal and public health. The blame for practically all deaths but those of old age is put squarely upon causes for which either individuals or the community are to blame.

But everyone who dies from any other complaint than old age, dies prematurely from an "unnatural" cause: and in the vast majority of cases, a premature death is a preventable death: hence, a disgraceful, because an unnecessary, death. The average

death is a reflection on the intelligence of somebody; either the victim, his family, or of the larger family, which is the community or society in which he lived. You may not believe this, so permit me to elaborate somewhat.

Under the popular "Believe It Or Not" challenge, the listeners are invited to test their own beliefs about certain widely held superstitions, fads, or half truths.

Some other good topics which approached public health from the point at which listener interest is greatest, are "How's Your Rheumatism?" "Wooden Indians" (about how ideas and knowledge have changed), and "Little Bugs and Big Bugs."

For the Three-year-old in England—Sir George Newman, in his *Annual Report for 1932*, as Chief Medical Officer of the Board of Education, urges

. . . local authorities throughout the country now to concentrate on the preschool child as they concentrated originally on the problem of infant mortality. He points out that the work of the school medical service is gravely prejudiced by the continued influx, year after year, of large numbers of young children suffering from impaired health and physique. Further, he writes: "The exceptional saving of infant life since 1910 has added to the population thousands of young children who, under less favorable circumstances, would not have survived. If, in addition to our continued neglect of the preschool child, we are also saving many physically and mentally enfeebled children, it is obvious that we must anticipate a heavy burden of defective children coming into the schools at 5 years of age."

In Durham County "an interesting and novel form of propaganda is being tried."

During the health week campaign in the county last year a number of the child welfare centers celebrated Health Days, and made each Health Day the occasion of a "Three-year-old Welcome Party."

A series of these parties is still in progress in the county. A card is sent to the mother of every three-year-old in the area served by the center, inviting her to the party, and

suggesting that as she will probably like to know her child's weight, and as there will be a crowd on the day of the party, opportunity is afforded for the weighing of children on a day preceding the event. A great many parents have risen to the occasion, taking the trouble to have their three-year-olds weighed on the day before the party.

It is much easier to get an idea of what the three-year-old population looks like if the children "process" alone, but, as the organizers of the parties found, it is by no means easy to get, say, a hundred lively and cheerful three-year-olds to form a procession, and it is surprising how soon a carefully arranged procession turns into a gay riot.

After the procession the mothers listen to an address, given by the medical officer of the welfare center, on the health and care of the three-year-old.

—*Mother and Child*, 5, Tavistock Square, London, W.C.1. Jan., 1934. 9d. a copy.

The Fifth New York State Health Poster Contest—This year the subject of the annual health poster contest in New York State was "Edible greens at little or no cost." The winning poster has as its slogan "Eat More Greens—They Are Nature's Best Tonic." A scholarship prize and three cash prizes went to high school art students. Further information about the posters can be obtained from the State Committee on Tuberculosis and Health, 105 East 22d St., New York, N. Y.

Health Education in the Journal—In *American Journal of Public Health*, July, 1934:

"Outline of Institute on Maternal Care by Victorian Order of Nurses for Canada."

"A New Deal in Health Education," by Bertrand Brown. The "basic task"; an institute of health education.

Eleven and One-half Per Cent—

The analysis of registration at the 1933, Indianapolis, meeting of the A.P.H.A. revealed that 53 out of the 456 members of the Public Health Education

Section were registered. This 11½ per cent was exceeded by 8 sections. One section only had a smaller percentage registered. Details in July, 1934, *Journal*, p. 754.

Is There Need for Nutrition Propaganda?—The National Baby Week Council, at a meeting in London, Nov. 15, 1933, discussed nutrition as a possible topic to be emphasized during the coming year. Dr. Eric Pritchard said:

The need for a spread of knowledge on matters connected with food and nutrition exists in all ranks of society. The newer knowledge of nutrition is beginning to invade all classes, but it advances slowly, and we should like to see the pace accelerated. Very complete knowledge does exist at the present time on these subjects, but it remains in the hands of the few, and requires far wider dissemination. This newer knowledge of nutrition includes certain general principles, the observance of which makes all the difference between good and bad health. The application of this knowledge does not involve, as a rule, any additional expenditure, but it does require more intelligence in the expenditure of that proportion of the income which is allocated to the purpose of buying food.—

Mother and Child, 5, Tavistock Square, London, W.C.1. Dec., 1933. 9d. a copy.

Lessons from the Past—Local and general history offer much material for attracting attention and emphasizing progress and how it may continue.

An extended article by W. R. Riddell illustrates anew the fascinating material to be found in the history of medicine and the health superstitions of the past—material which may lead readers into more prosaic information usable in the present day. In *Canadian Health*, 105 Bond St., Toronto, Ont., March, 1934. 15 cents.

"Health In Boston a Century Ago" is based on a study of vital statistics, suggesting the usability of similar Studies of other cities. *Statistical*

Bulletin, Metropolitan Life Insurance Co., New York, N. Y., April, 1934. Free.

Under "Then and Now," *Michigan Public Health*, Lansing (Oct., 1933), says:

The modern method of teaching health to children by putting it into their daily living rather than merely into their textbooks is a drastic change from the old way. In the library of the Michigan Department of Health is a "Catechism of Hygiene" published in 1893 and made up of 396 questions and answers. The preface suggests that these be "committed to memory as are the A B C's. They contain the essence of the whole science of hygiene, and, when they have been memorized, the pupil will be ready to take up the more advanced books on the subject and read them with understanding."

For the encouragement of those who may be inclined to question the newer method, we quote from the Catechism:

"Q. 68. What is the most unhealthful occupation?"

"A. Hotel waiters are the most unhealthy of all men.

"Q. 69. Why are hotel waiters so unhealthy?"

"A. Because hotel waiters are all the time eating the food and drinking the liquor that the guests leave at the table; they thus ruin their stomachs and destroy their health."

Material for Panel Discussion—

A page and a half of statements and questions were offered to panel and audience at a social hygiene session of the Annual Conference of State and Local Tuberculosis and Public Health Committees, State Charities Aid Assn., New York.

Horace H. Hughes, reporting the panel, says:

The participants in the panel discussion were sent mimeographed copies of these and other questions to be discussed several days before the Convention. They were requested to give their frank opinion. Several hours before the panel was held the chairman discussed informally with the various participants the general questions to be brought out. Copies of the questions were given to the audience.

Dr. Parran made the discussion as informal as possible. The speakers were seated on a

platform about one foot high in a semi-circle, facing the audience. It seemed to many observers that much more frank discussion of problems of social hygiene were accomplished by this method of presentation because there were no set speeches and each participant spoke as if he were conversing with a group of friends.

Of course, we found several difficulties which will have to be overcome if in the future this type of meeting is to be completely successful. The most important is the problem of maintaining the informality and yet having the speakers talk loud enough so that they can be heard in the rear of the hall. I think that the success of any panel discussion depends largely upon the chairman. He must maintain a fast tempo in the meeting and be thoroughly acquainted with the subject. We, fortunately, had an excellent chairman in Dr. Parran.

Copies of the discussion outline will be supplied by S.C.A.A., 105 East 22d St., New York, N. Y. Enclose return postage.

Health Education as It Is—The need for health education of adults, and what is done in a rural health district is presented by Dr. G. M. Little, Red Deer Health District, Alberta. Dr. Little gives a picture of what is done when there is one man for everything except nursing and sanitary inspection. (*Canadian Public Health Journal*, 105 Bond St., Toronto, Ont., May, 1934. 35 cents.) What is particularly needed is a detailed description of the job of getting health education done under such circumstances; what time is given to it; how to decide what to be done; what use is made of committees and other volunteers.

The health values of "Education Through Physical Education" are reviewed by J. E. Rogers in *Mind and Body*, New Ulm, Minn., March, 1934. 20 cents.

What a community should know about the local aspects of public information on social hygiene is a section of "Organizing a Community Social Hygiene Program." There are ques-

tions about what the health agencies do, the newspapers and the public library. In *Journal of Social Hygiene*, 50 W. 50th St., New York, N. Y., May, 1934. 35 cents.

"A Tuberculosis Survey" of Hawaii and Honolulu was two years old when it reached us, but the chapter on popular health instruction and publicity is worthy of mention as presenting what is, probably, a typical situation. Considerable use of various mediums is stated, but qualified by such phases as "no definite effort has been made to . . ."; "There is no coördinated plan of . . ."; etc. "In conclusion, the educational activities for the general public are rather unorganized."

They Know and They Do—"The Chief Duty of the Health Officer," is discussed by Dr. J. D. Applewhite, Macon, Ga., in *Southern Medical Journal*.

It is, of course, necessary that every well regulated health department have certain rules and regulations which require the citizens under its jurisdiction to do certain things and it is necessary from time to time to use the courts to force some individual to comply with them. However necessary such regulations may be, it is far more important that our citizens be so informed that they shall be anxious to comply with all reasonable requirements for their own and the public protection.

Published in full in *Bulletin*, Texas State Dept. of Health, Austin. May, 1934.

The A. M. A. and Health Education—A sketch of the organization and activities of the A. M. A., "The American Medical Association and Its Interest in Health Education," by Dr. W. W. Bauer, in *Journal of Health and Physical Education* (May, 1934), includes:

In 1911, long before health education was a popular subject, the American Medical Association established a Council on Health and

Public Instruction, which has since become the present Bureau of Health and Public Instruction. The purpose of the Bureau is to promote popular understanding of health and the relation of medicine to the public health through such media as *Hygeia*, *The Health Magazine*, pamphlet publications, radio talks, coöperative advisory relationships with lay organizations interested in health education, health exhibits, personal addresses by the Director, and by furnishing material for activities in health education to state, county, and district medical organizations. It also endeavors to further the periodic health examination. It answers thousands of letters every year, addressed to *Hygeia*.

In 1923, the American Medical Association launched a project which has proved to be unique, namely a magazine of national circulation devoted exclusively to authoritative material on health and health education. The magazine was appropriately named *Hygeia*. It was supported for several years at heavy loss and has never been a source of profit to the Association. It is dedicated to the purpose of enlightening the public with relation to health and medical matters and it represents the conviction of the medical profession that the public is entitled to such knowledge about health as can profitably be acquired by non-medical persons. The features of *Hygeia* are articles on various health topics from outstanding lay and medical authors; a department of school health; a juvenile department; a department of questions and answers; pictures of health interest from the far corners of the globe; health news and views in brief; and an advertising section which can be relied upon to be free from harmful exaggeration and misrepresentation.

The Association established a Bureau of Exhibits in 1930, which in addition to managing the Scientific Exhibit at the annual meeting and the permanent central scientific exhibit at headquarters, sends out numerous exhibits in connection with fairs, meetings, and conventions. These latter are of an educational nature and calculated to appeal to lay observers.

Reprints of the article, free. A. M. A., 535 N. Dearborn St., Chicago, Ill.

Classes and Conventions—Courses and convention topics on child health education are no novelty, but mention of courses and addresses on adult health education may well be recorded here as news.

Health education was given several periods on the program of the Annual Conference of Health Officers and Public Health Nurses and the Annual Meeting of the American Assn. of School Physicians, Saratoga Springs, June 25-30:

"Health Education in Rural Communities," by Gilbert D. Forbes, M.D.

"Health Publicity That Gets Results," by Elizabeth Wells, M.D.

"New Method in Public Health Education" (Demonstration of electrical transcription of radio health plays).

"What Can the Hospital Contribute to the Community Nutrition Education?" was presented at a meeting of Michigan Hospital Assn., and Michigan State Nurses Assn.

Rutgers University Summer Session Courses in Public Health Administration, 1934, will include Public Health Education, conducted by C. K. Blanchard.

The Flavor in Writing—Under this heading says *News Bulletin* of Social Work Publicity Council, 130 East 22d St., New York, N. Y. (June, 1934):

From Montreal comes a tip, not meant for copy, but highly applicable: "A year or so ago we had a convention of master bakers in Montreal and apparently there was a lengthy session on the difficulties of selling bakery cakes. One master baker got to his feet and said, 'I know why you can't sell your cakes. You put vanilla in all of them.'"

As vanilla is a too favorite ingredient in social work writing, we have selected this month some unvanillaed examples.

Then follow examples, including two from the health field:

Changing from direct-information-giving to conversational discussions will often vary your flavor. Our old friend, Ben Hustler, in the bulletin of the New Jersey Department of Health in *Public Health News*, March, 1934, has a nice informal way of mixing health information in with the repairing of pistons at his Piketown Garage. Mark Time, looking on at the repairs says that Ben is fine at remembering things, especially Board of Health rules: "Think of all I've forgotten, too;

those incubation periods, for instance. You could stick me on most of them now." "Me stick you," exclaimed Mark. "Why, I don't know yet what they are. What is an incubation period, anyway?" Hustler straightened up and pondered a few seconds. "It's the time it takes a disease to show itself after it begins to grow. Same idea as the incubation time for an egg." Mark knew about eggs. "You mean you set a hen on a clutch of eggs and in 3 weeks the chicks hatch out." "Yes, and when chicken-pox infection gets on the inside of a child, which is a sort of warm, moist, dark, incubator, in about 2 weeks the chicken pox hatches out—all over him." "Humph! I don't see much connection between chicken and chicken pox," grunted the assessor. "I mean they both follow the laws of nature which set certain lengths of time for things to develop," Ben answered. "The laws hold true whether it's disease or chickens, or 90-day corn or—." "Now let's see about this!" interrupted Mr. Time, becoming interested. "Suppose I was to get typhoid fever from some carrier who infected my food. Could you tell me when I'd begin to get sick?" Hustler worked a freshly oiled piston back and forth as he replied. "Sure, anyone who knew the facts could guess pretty close. You would probably begin to feel tired or so, have a headache and feel sick after 10 days, and go to bed and call the doctor about 2 weeks after you swallowed the germs."

In another health bulletin, the State Board of Health of Kentucky for March, 1934, we find another informal giving out of public health information. A public health nurse working in a pioneer field in Michigan exchanges letters with her old school mate, a rural teacher in the mountains of Kentucky. Each tells the other how a challenge in public health is being met in her own community. Right along with personal news and thanks for some cookies for which the recipe is requested, is such information as: "My immunities are coming up steadily and several schools are on the way to becoming budding health centers. Isn't it surprising what one can accomplish in the homes through the interest of the youngsters! I know that I have not used my teachers half enough, when, after all, they are the key people. . . . As I read your letter, I was aware that I should be stressing more the educational values of first aid kits in all my schools. . . . I'm going to bring in some country children to help in the demonstrations. . . ."

From Kentucky to Michigan goes the news of what happened after the Christmas vacation when the children reported on their trips

to the dentist, to the oculist and to the orthopedic surgeon as recommended by the school nurse. They both make fun of Asthma, the Michigan's nurse's car. Says the Kentuckian: "I can picture you in a cloud of steam, in snow to your knees, high zippers, and with burlap bags in front of your wheels, and you behind shoveling. . . . Just another month down here and the birds come back. . . ."

RADIO

Personal reminiscence is used by Dr. W. A. Plecker of the Virginia Department of Health, Richmond, to get attention to his radio talks. An incident impressed strongly on his mind when he was a child of 8 introduces the talk on "The Effect of Alcoholism on Longevity." An experience as a student personalizes a talk on the prevention of deafness. Other introductions use anecdotes or historical references which carry the reader by easy stages into subjects like "The Conquest of Rabies,"

"Diphtheria in a Happy Family," "Frontier Mothers," and "Fighting Typhoid with Peacock Feathers."

"The Trial of the Tubercle Bacillus," prize-winning radio talk for the 1933 contest conducted by Minnesota Public Health Assn., "is regarded by the contest judges as one of the cleverest and most effective ever presented in these contests." In *Everybody's Health*, 11 W. Summit Ave., St. Paul, Minn. March, 1934. 10 cents.

"Bleeding Gums—The Pink Tooth Brush," by Dr. W. R. Davis, opens with an incident and uses everyday illustrations. *Public Health*, Michigan Dept. of Health, Lansing. Oct., 1933.

"The Public and the Quack" is a friendly explanation of the quack and quackery, and how to avoid both. Connecticut Dept. of Health, Hartford. March 8, 1934.

A New Health Education Service

A NEW health information service in unique form has sprung up as an enterprise of the Association of Women in Public Health, a nation-wide organization of women professionally engaged in some form of public health or health education work.

For several months past a special committee has been active in securing, through the association members, fragments of authoritative health information. These have now been assembled in question and answer form and are

offered as the first installment of a continuing annual service with semi-annual revisions, by means of which the subject matter is kept up to date.

This service is designed to assist schools, colleges, public libraries, boards of health, nursing organizations and others who are concerned with public education in matters of health.

Further information may be obtained by addressing: The Health Knowmeter Committee, Department of Public Health, 100 Nashua St., Boston, Mass.

BOOKS AND REPORTS

A Review of Public Health Realities
—*Papers of Charles V. Chapin, M.D.*
New York: The Commonwealth Fund, September, 1934. 268 pp.
Price, \$1.50.

Dr. Chapin has enjoyed many and well deserved honors—the Presidency of the American Public Health Association and the American Epidemiological Society, the Marcellus Hartley gold medal of the National Academy of Sciences and the W. T. Sedgwick medal of the A.P.H.A., honorary degrees of Sc.D. from Brown and R. I. State College, and LL.D. from Yale. There is no honor more gratifying, however, than the publication of a volume of collected fugitive writings, for this means the preservation in lasting form of the essence of one's life. Two of Dr. Chapin's longer works, *The Sources and Modes of Infection* (1910), and *A Report on State Public Health Work Based on a Survey of State Boards of Health* (1915), have a fixed place among the classics of public health, and the present volume of collected papers should take its place by their side.

An illuminating foreword by Haven Emerson and an admirable outline of Dr. Chapin's life by C. H. Scamman precede the collection of 16 reprinted papers. Six are classed in the field of Public Health Administration, 5 under the head of Control of Communicable Diseases, and 5 as contributions to Epidemiology and Vital Statistics. It is of interest to note that 8 of the 16 papers selected for this volume were either addresses presented before the A.P.H.A. or were first published in this *Journal*.

Five of the papers seem particularly outstanding. *The Fetish of Disinfection*

(1906) and *Studies in Air and Contact Infection at the Providence City Hospital* (1911) contain the basic arguments of *The Sources and Modes of Infection*. *How Shall We Spend the Health Appropriation* (1913) initiates the second major line of Dr. Chapin's endeavors—a line which has borne direct fruit in the work of the Committee on Administrative Practice of the A.P.H.A. These two threads run through many of the other papers and constitute Chapin's outstanding contributions to sanitary science. He taught us that diseases come from persons and not things and that they are spread only by contact, food and animal carriers; and he inspired us to evaluate all our efforts in terms of concrete achievement in a way which has made public health at least approximately a quantitative form of social activity.

The other two papers which seem to the reviewer of most far-reaching significance along more special lines are *Deaths among Taxpayers and Non-Taxpayers* (1924), one of the most suggestive contributions to the vexed question of the relation between health and economic status; and *Changes in Type of Contagious Disease* (1926) the Sedgwick lecture which demonstrates so clearly the existence of variant types of infecting agents in smallpox and scarlet fever.

Perhaps the most important pages in the volume are those devoted to a bibliography of Dr. Chapin's publications including 133 titles. The 16 papers chosen for reprinting are admirably selected; but they may serve best as samples to tempt the reader to search out and study the rest. Dr.

Chapin's contributions to the philosophy and methodology of public health are greater than those of any living man. In the past only Frank, Chadwick, Simon, Shattuck, Sedgwick, and Biggs have perhaps made an equal impress upon public health practice throughout the world. The student of this subject will find in every paper he has written inspiration and sound guidance. The editor and the publishers have therefore rendered a splendid service to us all in the preparation and publication of this volume. C.-E. A. WINSLOW

Influenza. Part I.—By David Thomson and Robert Thomson. Williams & Wilkins, 1933. 640 pp. Price, \$12.50.

Students of the problems of bacteriology and allied sciences have learned to value the compilations issued by the Pickett Thompson Research Laboratory. Vol. IX is devoted to an arrangement and summary of the world literature dealing with influenza. It is not surprising that a subject so engaging to clinician, epidemiologist, and bacteriologist cannot be compressed into 700 pages; consequently the present volume represents but the first half of the vast undertaking.

The outstanding weakness of such a work is obviously that influenza is more of a name than a clinical entity, and the authors have been forced to include material dealing with a variety of disorders because exact criteria of diagnosis and identification are lacking. The casual reader is at once disturbed by the mass of conflicting data presented and the thousands of contributions written in the name of science which in the light of a more mature judgment hardly justify consideration. However, in this most complete of summaries, each point of view is so patiently and fairly presented that were it not for occasional gentle and skillful direction

on the part of the editors, a complete critical breakdown would ensue.

A volume of this kind is always impressive; not only is it a masterpiece in collecting and organizing knowledge, but it is in itself an epic, portraying through its very confusion mankind's gropings to solve and eradicate this and other natural scourges. That he has failed thus far in the instance of influenza must be admitted. In spite of the most careful study of bacteria associated with the disease, none, not even the Pfeiffer group, can be demonstrated conclusively as the primary etiological agent. Recent isolation of various filtrable viruses which attack the respiratory tract offers at present the best solution of the problem. Even more attractive is the hypothesis that these ultra microscopic agents may act in symbiosis with various pathogenic bacteria. In spite of the temptation to accept the virus theory which is strongly suggested by contemporary work, the editors maintain the same excellent critique which is characteristic throughout the entire work.

FRANKLIN M. HANGER

The Biology of the Protozoa—By Gary N. Calkins, Ph.D., Sc.D. (2nd ed.) Philadelphia: Lea & Febiger, 1934. 607 pp. Price, \$7.50.

Fundamental biological aspects of the unicellular animals, with observations on parasitic forms, are considered in a comprehensive manner in this volume by an author who has devoted many years to teaching and research. Illustrations are mainly from free-living forms. The concept, developed in the first edition, of a changing organization brought about by continued metabolism, has been amplified and furnishes the basis for an interpretation of life histories, biological phenomena of cell division, maturity, sex differentiation, fertilization, and senescence.

A new chapter on parasitism and disease has been added. Here are discussed effects of protozoan parasites on the host, parasitic flagellates including a list of species of trypanosomes, parasitic rhizopods, and the more important sporozoan parasites of man. The text is well illustrated with engravings and colored plates. This useful book has been materially strengthened by revision; it is carefully edited and well printed.

IRA V. HISCOCK

A Study of School Health Standards
—By *Anette M. Phelan*, 1934. Sold by the Book Service, American Public Health Association, New York, N. Y. 249 pp. Price, \$2.50.

This text is based on a questionnaire study of the opinions of 60 carefully selected individuals, whose official positions and activities would seem to indicate that they were competent to judge of the needs of a school health program.

Before arriving at the standards themselves, there is a good summary of much of the literature showing the development of school health procedures. This discussion and its bibliography are arranged conveniently in time periods.

After discussing the Problem, and Consideration of the Results as a Whole, there are presented chapters on the comparative merits of work done by professional and by lay workers, on the hygiene of the school plant, on the classification of children and special education, and on a group of other school health problems such as health of teachers and health education materials. The chapters on school plants, on classification of children and special education, and on the health of teachers and the use of health teaching materials are the most worth while of the text.

While there is much of value in this report, it is seriously weakened by the prolonged dull discussion of details as to procedure. The close adherence to

thesis making formulae is possibly responsible for this.

There is some duplication of statements that more careful editing should have eliminated.

CHARLES H. KEENE

Diseases Peculiar to Civilized Man: Clinical Management and Surgical Treatment—By *George Crile, M.D.* New York: Macmillan, 1934. 427 pp. Price, \$5.00.

In this book the author essentially continues his thesis of the kinetic drive which was developed a number of years ago. He has gone a step further and endeavored to show the essential physiological mechanism employed in producing a number of diseases peculiar to civilized man, such as neurocirculatory asthenia, hyperthyroidism, peptic ulcer, and diabetes. Elaborating upon the orthogenetic theory of von Nageli and Eimer, he strives to show that man has been developing along one peculiar line, namely, that of the brain, and that with this there has been a very marked development of thyroid and adrenal systems with especial development of the thyroid gland which tends to maintain emotional and mental activity at a constant high level as contrasted with the lower animals which need a more marked development of the adrenal system for a sudden energy demand in fighting, pursuit, or escape. Because of the over-activity of the hypothalamus, which genetically is the older part of the brain, and the center for emotional life, these organs are influenced by the sympathetic nervous system. In the more intellectually alert and emotional individuals there is likely to be too great activity of the adrenal system producing a lack of harmonic function. This in turn by increasing the activity of the hypothalamus, sets up a vicious circle which results in hyperthyroidism; increased activity of the islands of Langerhans causing diabetes; or the

rapid heart, cold sweaty extremities and fatigue of the neurocirculatory asthenia.

This book should be very stimulating to both the physician and the educated layman, as the approach to these diseases is considerably different from that of any other writers on the subject. However, the author has failed to consider some aspects of two important diseases: (1) the tendency of diabetes to follow acute infections as postulated by Allen, and (2) the very definite geographical distribution of hyperthyroidism. It would seem here that the thesis of the author has not fully explained their etiology.

E. D. BASKETT

Keeping Campers Fit: The Theory and Practice of Camp Nursing—

By Elena E. Williams. New York: Dutton, 1934. 227 pp. Price, \$2.50.

After an excellent summary of the needed qualities for success as a camp nurse and of the general scope of her "job," there are chapters on medical equipment in camp and for various types of trips, medicines most likely to be needed, emergency appliances, and treatments; a discussion of types of cases likely to be met varying all the way from poison ivy and camp accidents to communicable disease control; and technic of artificial respiration; and health and first aid instruction.

There is also a chapter on the legal responsibility of the nurse and one on preventive measures, such as physical examinations of campers—including height and weight—dietary care, respiratory, skin, and eye-ear infections, contagious disease control, and the control of fatigue.

This is an excellent text, evidently based on experience as well as on training. It should be extremely valuable, not only to camp nurses, but to camp directors and counselors and to others responsible for the health of camps or campers.

CHARLES H. KEENE

Introduction to Food Bacteriology

—By Andrew Moldavan, M.Sc. Lancaster, Pa.: Science Press, 1934. Distributed by the Author. 172 pp.

In the short space of 172 pages the author has endeavored to present a concise survey of the whole field of bacteriology, and of food bacteriology in particular. Much information has been condensed into a small space and consequently only one-third of the contents has been allotted to food bacteriology.

It is evident that a thorough study of the most recent literature has been made and that the author has sifted out that information which he considered most pertinent for use in this volume.

The book is too technical and condensed for the lay reader and would need supplementary explanation to make many points understandable to the average college undergraduate in science. For use in a short course to more advanced students well versed in the sciences, or as a means of review for the professional man, the book would be of value.

More care in the proof reading would have helped in eliminating numerous mistakes which detract from the quality of the book.

J. A. CLAGUE

A Health Program for the Children

of a County—By Thomas Gordon Bennett, Ph.D. New York: Bureau of Publications, Teachers College, Columbia University, 1933. 196 pp. Price, \$2.00.

This study assembles a mass of data which has appeared already in various reports and surveys from individuals and organizations, both public and private. The 5½ pages of fine print bibliography at the end attest this fact. Much of the material deals with school health programs and health education, although other elements are given due consideration.

The original part of the study is sup-

plied by a survey of the health conditions of Queen Anne's County, Md., for the year 1930-1931, and the application of accepted principles to the organization of a County Health Unit.

The chapter on the Health Center is well conceived and sets forth clearly, concisely, and to the point, the objectives, organization, administration, and financial support for a health center as it might be developed in a typical county. It is definitely stated that "the medical, social, and welfare service should function as a *complete unit* in the health program for the children of a county."

The method of presentation and format of the book follows the familiar pattern of the Bureau of Publications of Teachers College, Columbia University.

RICHARD A. BOLT

Industrial Toxicology — By Alice Hamilton, M.D. New York: Harper, 1934. 352 pp. Price, \$3.00.

This compact little octavo contains a wealth of material upon industrial toxicology, excellently organized, comprehensive, and tersely stated. The author is too well known in this field to need introduction, even to the rank and file of lay persons, at least those who read. Contrary to one's expectation, this book is not a mere abstract of the author's larger work on *Industrial Poisons in the United States*, but is quite an independent monograph based upon the author's own broad experience and no less than 655 citations from perhaps half of that number of investigators whose names have appeared within the "scientific era," and, of course, largely those of recent times. We noted many references as of 1931 and some later.

With a fitting introduction viewing the health of the working class and its protection against poisoning, the ten chapters are devoted to the principal industrial intoxicants. However, each

poisonous substance is considered as an entity in itself. The more important are given proportionate attention, while there is an adequate discussion of both sides of controversial matters.

A fairly close scrutiny has failed to find material errors. (We did note the undoubted substitution of the term "carbon monoxide" for "carbon tetrachloride" in the reference to Boveri on page 275, but the context would prevent misconstructions here.) While the range of authors cited is enormous for a book of this size, occasional important omissions can be noted, such as reference to K. B. Lehmann's rather extensive article regarding carbon tetrachloride in the *Zentralblatt für Gewerbehygiene*, u.s.w., May, 1930, the annual reports of the Committee on Lead Poisoning of the American Public Health Association, Oliver's "Dangerous Trades" (1902), and a very few others. Advisedly, we think, for the present time, the author has omitted any reference to silica and whether or not this substance is a "poison." Certain headings which the average practitioner might be seeking in the Index are wanting, such as "spray painting" and "duco," but practically everything to be expected is covered.

An especially commendable feature of the little volume is an alphabetically arranged author-bibliography which shows extensive inclusions from all languages, as well as an author-index for references used in the volume itself.

The author's easy reading style flows on most intriguingly, scarcely ever repeats, and is constantly in contact with its source material. The number of substances covered, from cause to treatment, should create a large demand for the book from all who could be possibly interested in the subject. It is written for physicians but a little use of a dictionary by the lay reader will bring most of its material within easy grasp—and surely in this day and

age, such should be considered a laudable step in self-education.

EMERY R. HAYHURST

Modern Drug Encyclopedia and Therapeutic Guide. By Jacob Gutman, M.D. New York: Hoeber, 1934. 1,393 pp. Price, \$7.50.

The above named book, as stated by the author, is intended for physicians, dentists, pharmacists, and medical students; and consists of "a presentation of 8,160 modern, non-pharmaceutical, medicinal preparations, comprising 1,878 drugs and chemicals, 535 biologicals, 860 endocrines, 1,563 ampule medicaments, 209 medical foods, 129 mineral waters, 2,344 individual and group allergens, and 642 miscellaneous products."

This array of therapeutic armamentarium gives an idea of the scope of the book and indicates how rapidly the number of therapeutic preparations is increasing. Of the making of them there seems to be no end. The busy physician cannot keep pace with such cumulative array, so he welcomes an up-to-date summary of new and old preparations together with their uses. Older physicians were taught to know a few drugs well, their indications and uses. Modern practitioners have at least to know a little about a great many new ones. For one disease listed in this book there used to be recommended half a dozen drugs or preparations, this volume names no less than sixty.

Dr. Gutman's book is a valuable reference book for the office or library. It claims to be unbiassed in its statements, by which is apparently meant that the general claims of the manufacturer of the product are set forth without criticism. Some of the preparations mentioned while effective for indicated ailments have been found to carry certain hazards, such as sensitization of the individual. No comment is made on these hazards. While a few

of the preparations belong to the class described by the authors of *100 Million Guinea Pigs*, most of them are Medical Council accepted.

The book sets forth, in order, drugs of known constitution and action, effective combinations, preparations of indicated composition, endocrine preparations, preparations of undeclared composition, endocrine preparations, hypodermic medicaments, biologicals, allergens, foods and beverages, bottled mineral waters, and miscellaneous products, together with a therapeutic guide containing indications for use of preparation mentioned. An exhaustive bibliography with indices is appended.

The volume is well printed and sizeable, considering the wide field covered.

JAMES WALLACE

Tuberculosis in the Child and the Adult—By Francis Marion Pottenger. St. Louis: Mosby, 1934. 611 pp. Price, \$8.50.

Back of this book is the ripened experience of a veteran tuberculosis clinician and crusader. It bears the benchmark of a good teacher—orderly sequence, familiarity with the work of others, and the clearly stated opinions of the author on all debatable and unsettled questions.

The student approaching the problem of tuberculosis for the first time as well as the well read specialist will appreciate especially the chapters on the chronological development of the disease. "Koch's phenomenon," understanding of which is basic to a working knowledge of tuberculosis, gave the impetus to extensive research work. But much that has been written about allergy, sensitivity and immunity is so confusing, if not conflicting, as to leave the student in a maze. Dr. Pottenger's clear description of the successive steps of tuberculosis from the time of the first infection, interpreted in terms of the response of the host to infection and

reinfection, helps to clear the picture. He may have his leanings where theory must bridge the gap, but he has obviously not been stampeded into extreme positions; the story holds water and enables one to understand the complex phenomena resulting from infection. With that as a background, succeeding chapters on the pathogenic changes, the symptoms predicated on them and the varying responses of the host to the tubercle bacillus, are equally illuminating.

There are few corners of the field which Dr. Pottenger has not personally explored, hence he writes with equal facility on the epidemiology, pathology, clinical technic, and surgery of tuberculosis. The critic might object that certain aspects are unduly dilated, leading one to suspect that the author is a hobby rider. He would doubtless point to the chapter on tuberculin therapy, the painstaking description of pulmonary reflexes elicited by palpation, the discussion of visceral neurology, but these are special fields in which the author has made original and pertinent observations. In fact, it is this feature of the book that lifts it out of the common run and places it in the distinguished merit class.

The illustrations, nearly all original, are of excellent quality and aptly fit the text.

H. E. KLEINSCHMIDT

Children, Young People and Unemployment, Part III. *The Save the Children International Union, 15, Rue Lévrier, Geneva, Switzerland.* Price, \$.50.

Part III of the series of inquiries into the effects of unemployment on children in Bulgaria, Esthonia, Finland, France, Hungary, Norway, and Sweden follows a presentation similar to the material in Parts I and II. Two special chapters on The Crisis and Juvenile Delinquency in Belgium by Paul Wets and Unemployment and Prostitution of

Young Girls by F. Sempkins are included.

While these reports are not exhaustive, they do give a fair picture of what has happened to the youth in these European countries as a result of the depression and unemployment. The conclusions sum up the series of reports: "We come now to the crux of the problem. It must be recognized that when parents cease to contribute in any way to the well-being of the child, and when food, clothing, care, love, all the child's needs, are provided *outside the home*, his relationship to his parents must obviously be affected; so, too, ultimately, the durability of the home and of the family. This must be kept in mind when we come to study the methods of welfare work necessitated by the crisis."

An appendix gives a tabular statement of relief measures which may be employed.

RICHARD A. BOLT

Medicine. A Voyage of Discovery —By Josef Löbel, M.D. Translated by L. Marie Sieveking and Ian F. D. Morrow. New York: Farrar and Rinehart, 1934. 341 pp. Price, \$3.00.

This is a well written book of unusual interest. It is a glorification of medical science, and sound reasons are assigned for giving it this exalted position. It is in a large sense a history of medicine, most of which is accurate, though unfortunately, some statements are not.

The author holds that the desire for knowledge probably found its first impetus in medicine, though he recognizes that the first researches were instituted on account of purely practical motives. There are chapters on the underlying sciences, since "a doctor must know something of every calling if he is to understand his own properly." The doctor must understand humanity and life as a whole, looking upon the individual as a link in the continuity of life.

"Anyone wishing to study medicine must first of all realize the fact that everything living forms a unity, that in nature there is but one difference—though indeed this is the greatest contrast of all—the difference between life and death."

The translation from the German appears to be excellent, though there are certain mistakes which one feels must be due to errors in translation or misunderstanding of the author's meaning.

On the whole the book can be recommended to doctors and especially to laymen, most of whom have no conception of the tremendous field which must be covered by the well educated physician nor of the equally large field which must be gained by contact with his fellowmen, especially those who are not entirely normal either through physical or mental illness.

MAZŮCK P. RAVENEL

The Pneumoconiosis Bibliography and Laws—By Davis, Salmonsens and Earlywine. Chicago: Industrial Medicine, 1934. 482 pp. Price, \$7.50.

The remarkable interest shown in the subject of pneumoconiosis stimulated by the exceedingly large number of claims throughout the entire country warranted expectation of an authoritative publication on the subject that would answer the needs of those who have made this subject their special field of interest. *Pneumoconiosis Bibliography and Laws* is a unique collaboration by a physician, lawyer, and reference librarian, resulting in the production of a reference work and source book that will be found to be both convenient and of immense practical value to those interested in the litigation of claims for pneumoconiosis or silicosis. Though the medical features are missing, this gap may perhaps be filled with a subsequent work on the subject.

The ambitious task set up by the

authors of this publication is divided into two sections. The first section on bibliography comprises two-thirds of the entire book, while the remaining section is confined to the subject of the compensation and common law as they relate to dust and its effect on the lung.

The bibliographical material is comprehensive and covers all the references that have both historical and scientific application. There are 2,768 references compared to 1,272 listed by the *Bibliography* published by the International Labor Office as of December, 1931. Not all the historical references are included. One by Martin Pansa, 1614, on "Diseases of Miners and Foundry Men in Annaberg," is not included. A few irrelevant references are noted. Such references as the *Textbook of General and Pathological Anatomy* and other references on lead poisoning seem out of place in a bibliographical account of this kind. The arrangement of the bibliographical material is excellent and many devices have been incorporated to aid the reader in quickly reaching references desired. The value of any bibliography, of course, depends chiefly on the ability of the authors to keep it up to date. The authors in their preface promise to do this by publishing subsequent editions of this reference work.

With regard to the section on Laws, a certain amount of confusion exists in that the title of the book would lead one to believe that the common law or compensation law with specific reference to pneumoconiosis would be considered. However, numerous decisions are quoted covering not only the wide field of occupational disease with such cases as dermatitis and lead poisoning, but also including other decisions with reference to the legal construction of the term "accident." There is, of course, a distinct advantage in including such labor laws as safety, hygiene and hour laws since they may have a direct bearing on

specific cases of litigation in pneumoconiosis. However, the title of the book gives no indication that the broad field of legislation as it applies to industrial hygiene would be covered. The decisions regarding lead poisoning and other occupational hazards are, therefore, essentially irrelevant. It would have been more appropriate to have confined these court decisions to those affecting alleged cases of lung fibrosis or pneumoconiosis alone.

One important decision in the case of the Pennsylvania Pulverizing Company vs. Butler, 61 F. (2nd) 311, is not in-

cluded. This is an important decision since it establishes a precedent in the field of occupational disease litigation that an employer must only exercise reasonable care and need not furnish any unusual or protective devices or information in protecting his worker.

The field of industrial hygiene is a vast one and its ramifications are many. It is difficult, therefore, to confine oneself to any single field. However, this study will have a distinct value for those who have the practical task of arbitrating and adjudicating these claims.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Brave New World—If you suffer from hardening of the mind, don't attempt this philosophic discussion about whither we are heading; but if you can survive the impact of broad ideas, treat yourself to this mental meal in which there is much red meat especially prepared for sanitarians.

COYLE, D. C. The Changing Order of Today. Pub. Health Nurs. 26, 7:565 (July), 1934.

Modern Health Administrative Measures—Valuable indeed is this brief, straightforward review of the newest public health practice in relation to diphtheria immunization, undulant fever, pellagra, and a dozen other health problems.

CUMMING, H. S. Some New Developments in Public Health. Pub. Health Nurs. 26, 7:358 (July), 1934.

Providing Medical Care—Adequate medical care and preventive services rather than benefits in lieu of wages lost through illness must have priority in any American scheme of sickness insurance.

DAVIS, M. M. The American Approach to Health Insurance. Milbank Quart. 12, 3:203 (July), 1934.

Adolescents' Hearts—In New York about 1 per cent of all adolescents have organic heart disease; a third do not know it. Adequate facilities for the care of cardiacs do not exist.

GOODMAN, M. and PRESCOTT, J. W. Heart Disease Among Adolescent School Children of New York City. J.A.M.A. 103, 3:157 (July 21), 1934.

Fall Colds—During the early fall months a higher than normal respira-

tory rate is associated with lower than normal temperature, a subnormal number of hours of sunshine and an increased relative humidity.

GOVER, M., *et al.* Time Distribution of Common Colds and Its Relation to Corresponding Weather Conditions. Pub. Health Rep. 49, 28:811 (July 13), 1934.

Wanted Babies—The economically fortunate families are practising contraception successfully and producing babies mainly as they want them. The families least favored economically make the least effort to control conception and their efforts are least successful. This is due primarily to ignorance of conceptive methods and not to the desire for large families.

PEARL, R. Second Progress Report on a Study of Family Limitation. Milbank Quart. 12, 3:248 (July), 1934.

Depression-Poor Children—Poor children contract communicable diseases earlier than children in better circumstances. But the "new-poor" have not been in straitened circumstances sufficiently long for their children to acquire the illness immunity of those of the chronically poor.

PERROTT, G. St. J. and COLLINS, S. D. Sickness and the Depression. Milbank Quart. 12, 3:218 (July), 1934.

Disease and the Injured Lung—The relationship of pneumoconiosis to tuberculosis has been studied extensively. This paper broadens the inquiry to include other infectious processes of the lungs. In general, the silicotic lung is more susceptible than the normal lung to any bacterial invasion.

PROSKE, H. O. and SAYERS, R. R. Pul-

monary Infection in Pneumoconiosis. Pub. Health Rep. 49, 29:839 (July 20), 1934.

Fate of Amoeba in Water Purification—Although *E. histolytica* cysts are removed from water by the accepted methods of filtration, chlorine in the amounts usually applied to drinking water will not destroy the cysts.

SPECTOR, B. K., *et al.* Effectiveness of Filtration in Removing from Water, and of Chlorine in Killing, the Causative Organism of Amoebic Dysentery. Pub. Health Rep. 49, 27:786 (July 6), 1934.

Lines of Attack Against Heart Disease—Rational methods of prevention against rheumatic fever and essential hypertension must be developed. Syphilitic heart disease can be eradicated. For the prevention of arteriosclerotic heart disease, there is little to be hoped.

STONE, C. T. The Mortality from Heart Disease: A Challenge. J.A.M.A. 103, 3:151 (July 21), 1934.

Nature's Handiwork—Studies reveal that overweight people have a

better capacity to endure prolonged strain than underweights. To this is appended the comforting conclusion that it is uncommon for overweight people to become underweight and *vice versa*.

TREADGOLD, H. A. Functional Efficiency and Body Build in the Young Male Adult. Lancet 1, 26:1377 (June 30), 1934.

Toxoid Immunization—Alum precipitated toxoid in one dose of 1 c.c. produced 100 per cent Schick negatives in the studies reported.

WALKER, A. A. One Dose Alum Toxoid in Diphtheria Immunization. J.A.M.A. 103, 4:227 (July 28), 1934).

Heat and Stopped Noses—Hill's observation that exposure to heat emanating from dark surfaces tended to close the nostrils was confirmed by this study. But his opinion that radiant heat did not produce the same undesirable phenomenon was not confirmed. Any heat will do it.

ASSOCIATION NEWS

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

- Thomas A. E. Evans, M.D., Farmers, Ky.,
Rowan County Health Officer
P. J. Fitzgibbons, M.D., City Hall, Amsterdam, N. Y., Health Officer
Roy O. Gilbert, M.D., 604 S. Maclay, San Fernando, Calif., District Health Officer
E. J. Latta, M.D., Gaston Bldg., Hastings, Nebr., City Physician
George N. Macdonell, M.D., City Hall, Miami, Fla., Director of Public Health
Dr. Manuel B. Marquez Escobedo, Paseo de la Presa # 37, Guanajuato, Gto, Mexico, Chief of Coordinated Sanitary Services
Perry A. Proudfoot, M.D., 220 Chestnut St., Roselle, N. J., Health Officer
Howard L. Sumner, M.D., Court House, Asheville, N. C., Buncombe County Health Officer
H. A. Tharp, M.D., Mansfield, La., Director, DeSoto Parish Health Unit
John D. Trawick, Armory, Louisville, Ky., Jefferson County Health Officer
Nellie S. Vernon, M.D., Associated Bldg., Astoria, Ore., City and County Health Officer

Laboratory Section

- Louisa H. Bacon, M.D., County Hospital, San Bernardino, Calif., Director, County Charity Hospital Laboratory
Alvin G. Foord, M.D., Pasadena Hospital, Pasadena, Calif., formerly Instructor in Public Health and Communicable Diseases, Univ. of Buffalo Medical College
Beatrice F. Howitt, M.A., Hooper Foundation, San Francisco, Calif., Research worker in Poliomyelitis
Evelyn M. Krayenbuhl, A.B., 1330 Mill St., San Luis Obispo, Calif., Bacteriologist, County Health Department Laboratory
John J. Miller, Jr., M.D., University of California, Berkeley, Calif., in Department of Bacteriology
Burr T. Snyder, City Laboratory, Sacramento, Calif., Director of Laboratories

- Fred Stimpert, State Board of Health, Helena, Mont., Director, Hygienic Laboratory
Harold A. Thompson, M.D., 907 Medico-Dental Bldg., San Diego, Calif., Bacteriologist, City and County Laboratory
Elsie Wattie, B.S., 8 Belvidere Ave., Worcester, Mass., formerly Biochemist, U. S. Public Health Service.

Public Health Engineering Section

- Walter C. Elford, 1213 S. E. Malden St., Portland, Ore., Chief, Division of Pure Food and Sanitation of Board of Health
Raymond F. Goudey, Box 240, Los Angeles, Calif., Sanitary Engineer, Dept. of Water and Power

Industrial Hygiene Section

- P. A. Bendixen, M.D., 512 Davenport Bank Bldg., Davenport, Ia., Designated Physician, United States Employees Compensation Commission

Food and Nutrition Section

- Paul F. Nichols, M.S., 336 Hilgard Hall, Univ. of Calif., Berkeley, Calif., Assistant Professor, Division of Viticulture and Fruit Products
Victor C. Morgan, B.S., 7445 S. E. 31 Ave., Portland, Ore., Chief Milk Inspector, Bureau of Health

Child Hygiene Section

- Amy L. Hunter, M.D., Dr.P.H., 17 Howe St., New Haven, Conn., Child Health Conference Work

Public Health Education Section

- Helen M. Baukin, Territorial Bldg., Honolulu, T. H., Supervisor, Dental Division, Department of Public Instruction
Florence Becker, 3301 N. Charles St., Baltimore, Md., Director, Dr. Bloodgood's Clinic
Lloyd L. Cullimore, M.D., 290 W. Center, Provo, Utah, Medical Director, and Health Education Instructor, Brigham Young University
Marietta Eurlon, R.N., 1266-7 St., San Diego,

Calif., Clinic Nurse, San Diego Tuberculosis Association
 Harriet M. Fitzgerald, 2325 Milvia St., Berkeley, Calif., Dental Hygienist, Berkeley Public Schools
 E. E. Gage, M.D., Sioux Falls, S. D., Superintendent, Health Department
 Reuben L. Kaufman, M.D., C.P.H., 543 Earlham Drive, Whittier, Calif., County Health Officer
 Caro Lane, South Georgia Teachers College, Statesboro, Ga., Teacher, Physical and Health Education
 James D. Lennahan, 25 West 43 St., New York, N. Y., Secretary, Life Extension Institute
 Roberto E. Peraza, Avenida Michoacan 36, Mexico, D.F., Mex., Medico Conferencista, Department of Health
 Lucy K. Proudfoot, R.N., 248-31 St., Hermosa Beach, Calif., School Nurse
 Margaret A. Squire, R.N., 1010 Washtenaw Ave., Ypsilanti, Mich., Public Health Nurse

Public Health Nursing Section

Anna R. Barlow, R.N., 223 N. 4 St., Reading, Pa., Director, Visiting Nurse Assn.
 Mildred C. Burgh, Coachella, Calif., Riverside County Nurse
 Marie D. Chambers, 113 S. Lake St., Madera, Calif., City School Nurse
 Rachel C. Colby, 205 W. Main St., New Britain, Conn., Director, Visiting Nurse Assn.
 Emma Donenwirth, R.N., City Auditorium, Canton, O., Supt., Visiting Nurse Society
 Mary D. Forbes, R.N., 302 Laurens St., Olean, N. Y., Director, Bureau of Public Health Nursing, Cattaraugus County Health Department
 Mary V. Gill, 1509 Washington St., Charleston, W. Va., Field Clinic Nurse, West Virginia Tuberculosis and Health Assn.
 Florence L. Hoffmann, B.S., 218 Holmes, Eaton Rapids, Mich., Teacher, Health Education
 Edith M. Holmstrom, State Dept. of Health, Iowa City, Ia., State Field Nurse, Bureau of Dental Hygiene
 Marie L. Kent, 2245 Central Ave., Alameda, Calif., Supervising Clinic Nurse
 Kathleen M. Logan, R.N., Rutherford County Health Dept., Murfreesboro, Tenn., Public Health Nurse
 Marion R. Long, 317 N. Milton Drive, San Gabriel, Calif., School Nurse

Gertrude Lyons, R.N., 6 B. Wilder Bldg., St. Paul, Minn., Director, St. Paul Baby Welfare
 Amy MacOwan, R.N., Palama Settlement, Honolulu, T.H., Director, Nursing Department
 Margaret Mallett, R.N., 66 Safford St., Wollaston, Mass., Public Health Nurse
 Emma Maurin, 223 New Court Bldg., New Orleans, La., Field Nurse Adviser, State Bd. of Health
 Ruth McGregor, R.N., P. O. Box 1193, Bisbee, Ariz., Cochise County Health Unit Nurse
 Mabel G. Munro, A.B., 210 Corby Bldg., St. Joseph, Mo., Director, St. Joseph Org. for Public Health Nursing
 Jane D. Nicholson, R.N., 2398 Sacramento St., San Francisco, Calif., Supervisor and Instructor of Public Health Nursing, Stanford University Hospital
 Clara Ross, B.S., The Rutzler, Charlotte, N. C., Director of Nursing, Charlotte Coöperative Nursing Association
 Luella L. Ross, 25 Ridgewood Ave., Wheeling, W. Va., Supervising School Nurse
 Molly B. Smith, City Hall, Bay City, Mich., Director of Public Health Nursing, Service of the Civic League
 Agnes G. Talcott, 116 W. Temple, Los Angeles, Calif., Director of Nurses, City Health Dept.
 Katharine L. Tuttle, R.N., 565-21 St., San Diego, Calif., Executive Secretary, and Director, Visiting Nurses
 Eva S. Waldron, 247 Union St., Springfield, Mass., Director, Visiting Nurse Association
 Anne M. Weir, R.N., 311 Lloyd Ave., Santa Barbara, Calif., School Nurse

Epidemiology Section

Joe S. Haskell, M.D., C.P.H., 1340 Monticito Drive, Los Angeles, Calif., District Health Officer

Unaffiliated

Robert W. Meals, M.D., 6777 Hollywood Blvd., Los Angeles, Calif., Attending Staff, Los Angeles County Hospital
 Frank T. Powers, New Street, Glen Cove, N. Y., Tuberculosis Case-finding by X-Ray Survey Method (Assoc.)
 Anna E. R. Robinson, M.D., 36 Clark St., Brooklyn, N. Y., District Health Officer
 Charles E. Smith, M.D., D.P.H., 2398 Sacramento St., San Francisco, Calif., Assistant Professor, Dept. of Public Health and Prev. Med., Stanford Univ. School of Med.

NEWS FROM THE FIELD

DR. PETER DIRECTOR OF NAVAJO RESERVATION

W. W. PETER, M.D., Fellow and Life Member of the A.P.H.A. has been named by the Indian Office as Medical Director of the Navajo Reservation. He will function somewhat as a state health officer with the physicians of the various agencies throughout the territory corresponding to county health officers.

Dr. Peter has seen public health and medical service in many lands, including China, the Philippine Islands, the Malay States and near eastern countries. He served as the Director of the Council on Health Education; as Honorary Secretary of the China Central Committee of the American Red Cross; he was a member of the Chinese and Foreign Famine Relief Committee; Assistant Secretary of the American Public Health Association; Director of the Health Service of the Cleanliness Institute; and technical adviser to the Ministry of Health of China. He has lectured widely and is an authoritative writer on public health and health education.

The Navajo Reservation contains 25,000 square miles and has a population of about 45,000. The Navajos, like most American Indians, have a peculiar susceptibility to tuberculosis, and the incidence of childhood cases is high compared to that of the white race. Trachoma, too, has for many years taken a heavy toll from the Indian race. Control of these diseases constitutes a major problem on the reservation.

Dr. Peter will organize field clinics for the early detection of tuberculosis and set up a system of home instruction

in disease care. He will attempt to segregate trachomatous children in boarding schools where they will receive regular intensive treatment, keeping the unaffected children in the day schools where they will be shielded from infection.

In time it is hoped to make a comparable attack upon the venereal disease situation.

It is the plan to interest leading Indians in every community in health problems. Local boards of health will be established with a representation of Indians on them, and Indian sanitary inspectors are to be employed. Already one Indian public health nurse has been trained and sent into the field. It is felt that by placing the responsibility of health largely on the Indians themselves a real attack can be made upon disease among the Navajo.

Memorandum, Office of Indian Affairs, Dept. of the Interior, Washington, D. C.

SICKNESS INSURANCE OF SCHOOL CHILDREN IN SWITZERLAND

SICKNESS insurance of school children, as a supplement to insurance of adults, is required by law in 8 of the 25 cantons of Switzerland, among them Geneva and Saint Gallen; in 7 other cantons, including Bern and Zurich, such insurance is required only in some communes. In several cantons the insurance law applies only to children attending kindergarten or elementary public school; in others it applies to all children of certain ages, whether they attend school or not.

Each insured child pays into the insurance fund about 15 to 20 francs annually (\$2.80 to \$3.80); in case of poverty the payment is made by the commune; in addition the federal

government and the cantons contribute together about half of this amount.

The purpose of the insurance is to provide medical attendance and medicines in case of illness or accident; also when necessary special kinds of treatment, such as ultraviolet-ray, X-ray, or orthopedic. Undernourished children and those in need of recuperation or rest are sent to special resorts in the country or in the mountains. Parents or guardians failing to insure their children or wards are subject to penalties.

The number of insured children increased from 25,000 in 1914, when the social insurance law of 1911 went into effect, to 338,000 in 1932. According to recent reports from Switzerland, the system of children's insurance has been working well. The expected reserves have been accumulated; large numbers of children have been sent to rest homes; and the sick children have been supplied with all the necessary treatment.—*Le Assicurazioni Sociali*, Rome, 1934, No. 1.

DEATHS

MISS ELIZABETH A. GREENER, principal of the School of Nursing and superintendent of nurses at Mount Sinai Hospital, died July 26th at Montclair, N. J.

For the last 2 years she was president of the New York State League of Nursing Education, and she had been president of the New York State Nurses Association. She was one of only 3 nurses ever to receive the French Government's decoration of the *Medaille d'Honneur de l'Hygiene*, conferred on her in 1927 in recognition of her contributions to the field of the nursing of children.

THE death of Dr. E. L. Cornman, President of the Gilliland Laboratories, Marietta, Pa., came as a great

shock. He had been in bad health since November, 1933, following an accident in the field at a dog trial. His condition had progressed favorably and he was considered out of danger and on the road to complete recovery. His death at the last was quite sudden.

Dr. Cornman has been a member of our Association for 8 years. He has been a strong supporter of the Association, always had an exhibit for the Gilliland Laboratories at our meetings, and attended regularly himself. He was a graduate of the Veterinary Department of the University of Pennsylvania. He will be mourned by a wide circle of friends not only in our Association, but in the American Veterinary Medical Association of which he was a prominent member.

HEALTH SERVICE IN ALASKA

DR. VANCE MURRAY of the U. S. Public Health Service, recently detailed to the Indian Bureau, has been appointed Medical Director for the Alaskan Indian territory.

A dentist, 20 hospital nurses, 23 village and traveling nurses, and 6 doctors carry on the Indian Service medical work in Alaska. They will all be supervised and directed by Dr. Murray. Besides this group of government people, there are a few private physicians and medical missionaries, and most of the salmon canning factories maintain a physician.

Over a territory extending from Juneau, his headquarters, Dr. Murray will travel as far as Point Barrow, at the extreme northern tip of Alaska, supervising and directing the Indian medical work.

NEW YORK STATE NURSES' CONVENTION

THE NEW YORK State Nurses Association and its affiliated bodies will meet in Buffalo October 15 to 19

in annual convention. The general theme of the program will be "The Nurse and Community Relationships."

Among the many speakers scheduled are Dr. Thomas Parran, Jr., Dr. Donald Armstrong, Clara Quereau, and Dr. George Ruhland. Mrs. A. L. Hansen, 181 Franklin Street, Buffalo, is general chairman of the convention committee.

PERSONALS

EVART G. ROUTZAHN, F.A.P.H.A., will, on October 1, retire from the active staff of the Russell Sage Foundation of which he has been a member for twenty-two years. Happily this means no diminution of his service to the many and varied extra-mural activities with which he has long been identified. Social work and public-health education will continue to enjoy his contribution to their graphic and popular interpretation.—*Survey*, Aug., 1934.

JOHN HALL, of Freehold, N. J., member A.P.H.A., has been elected Executive Secretary of the New Jersey Health and Sanitary Association.

DR. ZACK P. MITCHELL, of Weldon, N. Car., has been elected Health Officer of Vance County. The county has been without a health official since the resignation of Dr. Crete N. Sisk, of Henderson, the early part of the year.

DR. FRANK S. FELLOWS, of the U. S. Public Health Service, who is now medical director of the Indian Bureau in Alaska, has been transferred to the southwest (territory including Arizona, New Mexico and southern Colorado) with headquarters in Albuquerque, N. Mex., to succeed Dr. Langdon R. White, who has been transferred to the territory surrounding Minneapolis.

CONFERENCES

Sept. 2, State Laboratory Directors' Conference, for Directors of State Laboratories and their principal assistants only, University Club, Pasadena, Calif.

Sept. 3-6, 63rd Annual Meeting, American Public Health Association, Pasadena, Calif.; headquarters, Huntington Hotel and Maryland Hotel.

Sept. 4-6, 9th Conference of the International Union Against Tuberculosis, Warsaw, Poland.

Sept. 10-13, 13th annual scientific and clinical session of the American Congress of Physical Therapy, Philadelphia, Pa.

Oct. 8-10, Annual Meeting of the Association of Military Surgeons of the United States, Medical Field Service School, Carlisle Barracks, Pa.

Oct. 15-18, 17th Annual Meeting of the American Dietetic Association, Washington, D. C.

Oct. 15-19, American College of Surgeons, Boston, Mass.

Oct. 15-19, Annual Convention, New York State Nurses Association and its affiliated bodies, Buffalo, N. Y.

Nov. 13-16, Southern Medical Association, San Antonio, Tex.

Nov. 16, 17, 60th Anniversary Meeting, New Jersey Health and Sanitary Association, Berkeley-Carteret Hotel, Asbury Park, N. J.

Dec. 27-30, Annual Science Exhibition of the American Association for the Advancement of Science and Associated Societies, Pittsburgh, Pa.

April 29-May 3, 1935, 19th Annual Clinical Session of the American College of Physicians, Philadelphia, Pa.

Public Health Awaits Social Courage^{*}

HAVEN EMERSON, M.D., F.A.P.H.A.

President, American Public Health Association, and Professor of Public Health Practice, De Lamar Institute of Public Health, Columbia University, New York, N. Y.

SCIENCE in its varied and attractive aspects will be offered to you at this, as in former meetings of our Association, by competent and industrious devotees and contributors. History, prophecy, organization, the progress of our art, former and current triumphs in disease prevention, all have been amply and handsomely dealt with by my predecessors in this honorable office.

It will be my pleasure, even at the risk of yours, to offer you opinions rather than rigorous fact, and to tempt you, if you will let me, to look at the necessity for courage as well as knowledge, for the will-to-do, and, when indicated, the decision not to do, as our people may require. I offer you therefore the title "Public Health Awaits Social Courage."

Our concern is with the use of biological knowledge through the instrument of civil government, and with the authority which this exercises through laws and public education over communities organized voluntarily, and

served by their representatives freely chosen. It is the use by man of natural forces, his conquest of other living things for his own security that distinguishes the civilization which we share in today from those that preceded ours, back into the earliest records of human accomplishment.

If the tendency of the succeeding waves of civilization to be of longer duration, and of the intervals of barbarism to be briefer, is to be maintained, it will come about apparently more through increasing wisdom in the control and processes of human life than by the agencies of wealth, and power over material things.

The natural sciences have been harnessed to and by society for generations, but in the more distant past as a means to physical strength and possession, or for the command of the wherewithal of food and shelter, rather than intentionally and specifically to triumph over sickness, to guarantee infant survival, and to enlarge the quantity, and ennoble the quality of human life, by removal of any hindrance to its security. The wisdom and ingenuity of breeders, the skill and trained imagination of horticulturists

^{*} Presidential Address delivered at the First General Session of the American Public Health Association at its Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

have sometimes brought such superabundance of food upon us that national surfeit has been commoner than famine. We actually from time to time find ourselves embarrassed by the paradox of our plenty, and have been occasionally all but smothered by a plethora of sustenance.

It is upon the Department of Health of every political unit of area and population in the modern world that a splendid charge is placed in our trusteeship; guardianship of life for the benefit of each human soul and body within the respective jurisdiction.

From the least, the simple group of village, town or county, up through city, state, and nation, to the culmination of hopeful collaboration over the five continents of the earth through the League of Nations, the duty is the same; the knowledge is identical; only the need and the selective appropriateness of application vary as race, climate, and ways of work create different problems and determine the resources to meet them.

It is not for us to assume an expertness in the economics of production, of transport, exchange, or profitable disposal of that wealth which water and warmth wring from the surface of the earth, nor yet ours the burden to play the rôle of social engineers bent upon ending perennial or periodic poverty. It is enough that we have chosen a way of life, and an arduous preparation to fit us to know how families and communities can accomplish their destinies with least human loss or damage. This we achieve with but uncertain and indifferent success by the art and science we call public health. It is not the biology of agriculture and animal husbandry I would select for discussion today but the use of natural history for the sake of human history which I would persuade you has made romance of contemporary social progress. To quote a philosopher of a hundred years

ago "Natural history by itself has no value, it is like a single sex, but marry it to human history and it is poetry." It is this poetry which entrances us and pledges our continuing loyalty to our profession.

It would be as trite as it is tempting to review the triumphs of our nation, of our maelstrom of races, of both sexes and every age, in the steady forward progress of life security within the existence of this Association. Abler presidents than I have raised the applause due to giants of sanitation, to disciples of bacteriology, to patient plodders in personal hygiene. It is enough to recall that progress has been all but continuous, uninterrupted, and cumulative in its pace, reaching a new zenith in these past 5 years of colossal economic confusion, of frustration of finance, of collapse of commerce, of arrest in industry and labor.

Let me rather accompany you into that discipline of mind, and through that humility of spirit which comes from attempting to foresee the future, looking for new triumphs, and seeing in the failures of today a most precious experience for our successors.

If I were challenged to describe the elements necessary to assure further improvement of human health in our associated nations, these three would seem real and pressing: some increase in effective intelligence; something of the spirit of religious devotion even to the point of self-denial in the material possessions and accessories of today's life; and lastly, courage to apply what biology has taught us to believe.

In the matter of raising the general intelligence level a little, our rôle can be only secondary, as of any other professional group. That shrewd historian, Kirsopp Lake, observed "If the general intelligence rate rises even a fraction of one per cent, that rise constitutes a revolution in social condi-

tions." It would indeed be evidence that no mean fraction had been gained if tradition, superstition, a certain herd or sheep-mindedness of our people were replaced by reasoning based on objective observation of fact, and by a habit of thought which leads to controlled experiment for answers.

The Moro warrior who asks to be vaccinated because he sees his children saved from smallpox, the South Sea Islander who crowds the clinic to experience the miracle of arsenical treatment for yaws, has from the biological point of view attained a level of intelligence far beyond that of the silly thousands of our fellow citizens who trust their pseudo-consciences rather than the doctor's brain, their religious creed instead of nature's evidence.

Our part in lifting the intelligence level will always be a modest one, but we can none the less add a bit to the pressure upward. We can speak with reverent honesty of the truths of life so that there will be utter and consistent trust in our facts, in our reasoning, and in the certainty of our conclusions.

Better silence and patience than the glib inaccuracy of prolific popular promoters.

It is a very present need that half-truths, however popular, do not appear in health bulletins, that none but modest claims be made for prevention or treatment of disease. Rather let the application of a new truth lag by months behind the record of successful experiment than have to excuse the falsehood of a premature publicity about some uncorroborated claim of discovery. Intelligence levels will never rise while the spoon-fed multitude is persuaded out of its earnings by specious and deceptive advertising.

Complacent acceptance of obviously false claims of healthfulness for foods, drugs, soaps, cigarettes, candies, cough drops, illuminated milk, ice, bread, and porridges, challenges our standard of

truthful education in the community. No health officer or agent, however humble, is doing his or her share in blocking error and stimulating critical thought and useful action, if he does not use his public authority to refute the false claims of advertisers of foods and drugs, and a multitude of pseudo-health contraptions. I see no excuse for temporizing with the advertiser when his sales talk is in direct or implied opposition to fact. The society that trusts you to protect it against bacteria and their vectors will support you when you raise your voice and use your powers to frustrate that most noisome of human insects, the man who sells his goods on a false fear of illness or on a futile hope of health.

Even if the Tugwell Bill, a splendid gesture for new liberty of the consumer from food and drug abuse, did not this time become law, at least the State of New York has found it possible to levy upon an industry and the taxpayer to advertise the high worth of a precious product. New Yorkers are investing half a million dollars in governmental advertising of milk, an innovation in functions of state government which might well extend to other essentials so that car cards and radio nonsense may be shamed, or replaced by simple truth. Better emphasize the good than enter controversy with the vicious, but let us at least be not indifferent to error and deceit in the marketing and advertising of foods and drugs.

It is not the authority of the law, nor new knowledge, nor efficient organization, nor even money that is needed, but opinions based on fact, ideas grown in reason, concepts, declarations of independence from the trammels of outworn tradition, of abusive repetition of all too common customs, that will lift intelligence levels and force the salesman and advertiser to be truthful, and to that extent honest.

Power of publicity, of free access to

the eyes and ears of the thoughtless multitude, if divorced from a sense of responsibility to the consumer, to the group, to the social order, is as great a menace as polluted water or unpasteurized milk.

As to self-denial, even to some extent a religious or emotional devotion or self-sacrifice, let me express a personal preference for attaining our objectives rather by going without some things than by "go-getting" everything to be had. A natural practical philosophy of the pioneer, of the pampered pupil of plenty, is spending oneself into perpetual prosperity. Perhaps this has been a safe, successful and useful principle of personal and public conduct in the infantile, the immature period of rapidly expanding population, with immigrant and birth rates both high. With today's ageing population, with the largest state population already showing an annual loss among its native born population of one-half of one per cent, an increasing discrepancy between production of wealth and its expenditure for the lengthening education and maturity of youth, and for an increasing span of age and decrepitude, will force us to a choice between sacrificing some of our accessory, costly but superfluous and unnecessary expenditures, or abandoning our investments in health and culture.

Taking only 5 major items of individual expenditure, wholly within the choice of each of us to forego, to reduce, or wholly to omit, and recognizing that no one of these objects or costs contributes to any material degree, if in fact at all, to the personal or racial health or benefit of our people, we find that approximately 9 billion dollars are spent annually in this country for tea, coffee, tobacco, alcohol, and cosmetics (including services). It is not that I would condemn these expenditures as vicious, sinful, or wasteful, but that, as

between the satisfactions they bring to the spender, and those which half this cost would bring if devoted to investment in the use of applied biology to human health, there is a lack of a sense of proportion, of intelligent choice, and thrifty discrimination.

We cannot now or in the reasonably predictable future have all the purchasable accessories at our tables, each contrivance for physical convenience in our homes, the latest speeds for individual transportation, the problematical delights of universal intercommunication, and also command the facilities, the personal services, the benefits in home and work of that use of natural science in the everyday life of work and play, profit and pleasure, which public health in its broadest sense can bring to a certain fruition.

The greatest effectual block against the minimum essential, the moderate but desirable, and the optimum advantageous expenditure by individuals and the community for personal and public health, is not ignorance, not politics, not religious or antisocial antagonism, but the competition of commercial advertising, the pressure of personal pleasures for the cash in the consumer's pocketbook, the inertia of spending habits.

To meet this competition is needed, not more advertising, not an increase in competitive promotion of services and products, but a serious will to attain the more enduring satisfactions, the deeper securities of life, the necessities of cleanliness, nutrition, recreation, leisure upon which a more rational way of life can be based.

If a per capita annual expenditure of \$72 has been by habit, inclination, and commercial persuasion, saddled upon our people for dietary drugs, for the brief comforts of taste and smell, for the evanescent mask of painted pulchritude, a moderate self-denial would permit enough diversion of funds to finance

the most ambitious scale of expenditure for personal and public health which the imagination and proposals of competent persons has yet expressed.

I see no likelihood of new money being freed for constructive social and cultural progress otherwise than by going without some of the current self-indulgence, and furthermore in such modest self-restraint for health there would be a distinct contribution to that still intangible and distant hope, better mental health.

It is by self-control and self-restraint that man is chiefly distinguished from the brute. Reduction in the use of dietary drugs, in the facile deception of an imitation of honest loveliness would of themselves add a stronger quality to contemporary behavior.

I would not particularly emphasize the leading rôle only of these 5 unproductive objects of common expense, but more that gluttony in foods, waste in the fallacies of the shifting fancies, and a general slovenliness and unthriftiness among our people readily account for sums which in some Utopian existence might be diverted to the luxury of health.

If we would grow, progress, and truly enjoy the precious treasures of life, we will doubtless find it necessary to choose between these and the flitting accessories of an artificially desirable manner of life. If security, beauty, leisure to think, and to add to the durable satisfactions of life, are our choice, we shall attain them only by voluntary and determined sacrifice of what Plato called the appetitive forms of desire. After all, individual choice and the use of it is the distinction between a culture, a government, a society of tradition or slavery, and one with the ambitions of those democracies which our Association represents.

Self-denial in small things would be a good promise of achievement of communal restraint in great affairs.

How can we expect to abandon war as a social debauch, a mass anesthetic, a moral depressant, really an exhilaration of formally approved violence and murder, if we have not learned to live our individual lives without the aid of drugs?

Let us also practise self-denial by refraining from the use of fear as a motive of self-protection, of personal conduct, and personal hygiene. Avoid threats of disease as arguments for good conduct. Use instead appeals to intelligence, and worthy use of the body and its life as entrusted to us. Let us deny ourselves the emotional indulgence of campaigns against non-essentials. Distinguish between the annoyance of noise, the unesthetic effect of untidiness, and the violence to health and safety in gluttony, self-drugging, and over-crowding. Let us get worked up over spitting, but leave litter abatement to housekeepers. Lend a sympathetic ear to those who believe their irritability results from other people's noise, but raise particular hob if any privy is unsanitary. Hold to the course of essential sanitation before sharing with those who fuss over outdoor dustiness and smells and robust racket.

As to the last of my suggested trio of collaborators for an ampler national health; courage to invent, to test, to apply; courage of society to demand those services which science is ready to perform; let me remind you of a phrase from his *History of Civilization* by the pre-Victorian historian, Buckle, "The great enemy of knowledge is not error but inertness. All that we want is discussion and then we are sure to do well no matter what our blunders may be"; and again, "The progress of civilization varies directly as 'skepticism' the disposition to doubt and investigate, and inversely as 'credulity' or the 'protective spirit' a disposition to maintain,

without examination established beliefs and practices."

For a stepping up of general intelligence our part though honorable must be indirect and very modest.

To develop a spirit of self-denial in small matters for the sake of great we can help by judicious exposition of the stock in trade of the medical sciences, and by our own example.

But in the matter of social courage for new health levels ours must be the vision, ours the leadership and the challenge of events.

Among a multitude of opportunities to play our own immediate part in the march upon social inertia or cowardice, I have selected several examples.

CLEANLINESS

First in order of sanitary and general social importance for all our populations outside of ordered cities is the age old problem of man's soiling of the surface of the earth. In great areas and for large population groups in the United States proper, more than half of the permanent homes are so equipped and conducted as to preclude the possibility of the most elementary form of personal cleanliness. Until man has so emerged from the level of the beast that he has learned not to make his own shelter, his garden patch, his dooryard, the pathway to and from his work, a source of continuous pollution of his and his family's food, feet, and water, he cannot be considered to have started on the climb to social security. That state and county is a rarity whose health officer can with knowledge and conviction claim that all living, working, school, play, and travel premises within his jurisdiction have such disposal of human waste as meets the simple necessities of decency and cleanliness, or can point to records of sickness and deaths free from those known to be due—and to be due solely—to transfer of feces to food.

It is not that we fail to record the triumphs of cholera control, of typhoid abatement, of great reduction in the diarrheal diseases of the young wherever the sanitary engineer has served the governments of cities. Nor is there reason to be ashamed of the past few decades of effort against parasitic infestations in rural areas of our continental and insular possessions. What should be obvious, but appears to me to be shockingly neglected, is that such a fundamental responsibility of our profession is but partially met. Satisfied with the easy success of sewer systems for the city and town we have passed on in cheerful confidence to other needs of congested centers. We cannot consider ourselves a civilized nation, nor imagine that we have attained even the safety of the Indian nomad with his shifting tepee, until each settlement, shack, house, or place of human habitation and use is so equipped that family and friends, guests, laborers, and travellers can meet the calls of nature without soiling the spot of land they occupy with infecting and infesting organisms. In this generation of frank expression, when few reticences remain of body or mind, of thought or act, let us be Elizabethan in the directness of our language, and insist that the sanitary privy be built before the house is occupied, and that taxes be not levied on any man too poor to build one for his own family.

We have travelled far from the inception of our public school system, when in the State of New York less than half of the schools had any provision whatever for the body wastes of children and teacher. And yet today it is true that even where chromium plated plumbing dazzles the eye and burdens the taxpayer, there are lacking the easy and practical conveniences for washing hands in most of our school buildings. Let boards of trade, chambers of commerce, local newspapers, the churches,

school boards, county supervisors advertise the need and the ambition to have their particular community recorded officially by local and state departments of health as having no home or place of human activity without sanitary privy and closely accessible water and soap. Let children learn in the nursery and school that health begins with cleaning their bodies for their own safety, and of washing their hands for the sake of others.

Here is a challenge to resourceful publicists, for those who prefer weasel words, to such as Chaucer used, a worthy object of campaigns, slogans, drives, and the like. We can point to a spiritual as well as a physical exaltation for the village which achieves a sanitary privy for every home. Let the city health officer advertise the amount of sickness, even in his well sewered community, which can be proved to be due to immediate or remote infection and infestation from bowel to mouth. There is hardly a Porto Rican of the 45,000 served chiefly by our free hospitals and clinics in New York, or a rural laborer from the South to Detroit's automobile factories who does not travel and live a walking museum of potential disease because of insanitary home conditions and personal habits. And the same can be said of other unfavored groups whether white, Negro, Filipino or Japanese. The safest place for these people is of course the modern city with its plumbing and its abundant water. But turn the city dweller into a hitch-hiker, into summer camper, into boarder, traveller, searcher for work, or back-to-the-lander, and he faces the eternal, the first necessity for health, decent disposal of his own body detritus with cleanliness to himself and safety to others. What is axiomatic soon develops social inertia, and it is something akin to this indifference that makes a people more devoted to the enameling of finger nails, and the creas-

ing of trousers than to the sanitary privy as a mark of social distinction. I should not wish any city or county or state to be permitted to compete for health distinction from the A.P.H.A. unless the health officer presented responsible evidence that within his jurisdiction no one lacked means of preventing soil and hand pollution.

The era of environmental sanitation began something that has not been finished. Around the world man's filth remains his health's greatest enemy especially where, as in large areas of the Orient, his necessity for food depends on the fertilization of his crops with human manure. With more than half the people in some of our southern states living at a sanitary level no higher than that of the domestic animals, it will take more than routine public health effort to clean up the mess that man's necessity has created. The cattle in many a certified dairy farm live under a technic of routine cleanliness superior in orderliness and esthetics, as in sanitation, to that in vogue among a large remaining fraction of our population which carries on in fact a hand to mouth existence in filth. I would not quarrel with colleagues who fear the running nose more than the running bowel, and it is a matter of some satisfaction that the peak of deaths and sickness has been shifted from midsummer, and lesions below the diaphragm, to midwinter and spring and the respiratory tract, but I urge upon you serious and sustained reconsideration of the problem of sanitation of fecal disposal as a major unfinished job for which ingenuity and determination, rather than more research or authority are needed.

SYPHILIS

Second only if at all in demand for courage is the pressure of conscience, of science itself, of past and present neglect, to make a frontal attack on

syphilis. Five hundred years of accidental acquaintance with this disease, precise and voluminous knowledge of its clinical manifestations, adequate and exact information as to specific diagnosis and cure, widespread and increasingly competent records of prevalence, universal conviction as to its devastating effects on families as well as individuals, powerful authority and generous voluntary assistance for control and education—these and a multitude of other factors crowd upon us as reasons to hope for, and to promise ourselves, the great achievement of washing the human race clean of pollution. If and when this is done we shall have added years to life expectancy, assured the birth of the wanted child, and created large vacancies in hospitals and asylums.

How can it be that in this instance our knowledge is largely sterile, our ambition thwarted, our strategy weak, the logic of our public conduct confused by traditional reticence. We have done almost everything except make an intelligent and consistent use of our present knowledge. Human instinct we have explained and emphasized, but in no respect altered. Character in youth we have tried to bend and mold to finer proportions and more unselfish ends, with but slight success. Social customs and the exploitations of commerce we have sought to alter or forbid by local and national law, and the power of the League of Nations, with but vacillating response from peoples and governments.

From babyhood to parenthood we have tempted curiosity to satisfy its craving through a newer, franker knowledge of life processes in flower, insect, pet, and human family. Euphemisms we have used in lecture, screen, and public print to save the blush of guilt or innocence and still patients and the reading public know little of the facts of origin, means of transmission, and course of the communicable disease syphilis. We have hinted, and hidden,

and yet hoped for results; and still this malign infection flows almost unrestrained through marriage as through brothel, in childhood, in maturity, and in age. It is of little moment that here and now you should be assailed by figures of incidence and death, by estimates, percentages and rates, by probable errors or significant differences; it is enough to have graven in your minds, ever present in your thoughts, ready for argument and action, that syphilis is the most prevalent communicable disease, and one for the prevention of which we are doing the least, although we have a reservoir of knowledge for instant practical use greater than that for combating any other disease, unless it be diphtheria, or malaria, or hookworm infestation.

We do not know in any substantial number of cases the time, place, source, or manner of infection. We do not know, except in a small number of persons, the presence of the disease at its onset. When we do learn this we fail to use reasonable resourcefulness to discover the person and conditions responsible for the case just reported. We allow patients known to be in the communicable and uncured stages of the disease to escape from supervision in enormous numbers from every syphilis treatment office or institution in this country.

We have no proof that any material reduction in general incidence has resulted from the past 20 years of increasing attention to syphilis as a social and health problem, although in groups of men under military discipline and among students wisely guided by college health services remarkable reductions in occurrence of the disease have been recorded. We know that so small an incidence as two-tenths of one per cent of syphilitic infection is to be found in selected groups of young men and women of university caliber, and that syphilis exists in recognizable form in

as high as 37 per cent of rural white and Negro populations of some southern states. Is it safe, is it compatible with the ambition of our day that there should be any such inequality in disease prevalence in any country where public education is supposed to be the right of every child, and protection of the people's health the first duty of statesmen?

The habits of a large proportion of our people, the insistent pressure of commercialized prostitution aided by the greed of landlords, corruption of courts, and connivance of police, the biological urges of the animal in man and woman, combine to make the problem one of extraordinary difficulty; but the answer would appear to be a direct medical and sanitary attack, so reasonable, so logical, and so sustained as to rouse the public in support, and to challenge today's society to a courageous consideration of human values and prevailing liberties of conduct. What has been accomplished in control of other communicable diseases of man by determined use of medical knowledge can and must be done with syphilis or we are unworthy of our predecessors.

MARRIAGE COUNSELLING

Closely related to the problem of syphilis which is primarily one for physicians, sanitarians, nurses, and educators to solve is that of a health service for marriage advice, primarily in the social interest of family security, but inseparable from medical, legal, and educational implications.

From the early, much criticised, highly controversial, sometimes legally interdicted efforts to translate into common usage by married women and their husbands, through offices or clinics, frankly contraceptive information, by persons of medical or less competent qualifications, there has been abroad and in the United States a steady growth in the understanding of the useful functions such agencies might serve,

the social and educational, and preventive medical concern they have for a mature society, and the auspices under which they may safely be operated.

Since the origin of marriage counselling in 1922 under public control in Vienna, the German speaking countries of Europe have developed a total of 1,100 such centers, of which 900 are under private auspices. The first official bureau was opened in Berlin in 1926; Switzerland opened official marriage advice bureaus in Zurich in 1931 and Basle in 1933. Approximately three-quarters of those who come for advice are concerned with problems of sterility, contraception, therapeutic abortion, and medical conditions contraindicating pregnancy; the majority of the remainder seeking information on questions of inheritable and congenital defect and disease, where mental abnormality, tuberculosis and syphilis exist or are suspected in the family; and a substantial number are concerned with the physiology and pathology of sex adjustment, before and during wedlock. These stations are under some appropriate legally recognized religious, health, educational, or other professional auspices such as we are familiar with in the origin and promotion of prenatal, baby health, tuberculosis, and venereal disease clinics in this country.

In Germany, the school physician is usually in charge and acts as the key person and intermediary between the various medical and social agencies called upon for services. In addition to the official municipal centers, numbering about 200, sickness insurance funds operate a considerable number of marriage advice stations, but most of them are under private auspices, and are supported largely on a service basis by membership fees. On the whole, applicants to these centers are from among the working classes who are unable to pay large fees for diversified services.

Departments of health in many of

the smaller cities (Dresden, Lübeck, Hamburg, Lenz) coöperate with the local sickness insurance funds in operating these centers.

In Freiburg in such a bureau in the Woman's Hospital connected with the University Medical School, advice is given to Roman Catholic and Protestant patients by the same physician, but at different sessions, to permit appropriate collaboration of the priests of the respective churches.

Under Roman Catholic Church auspices women's groups have 50 such centers scattered about Germany. The Protestants have 13, and the Jewish women 2, the applicants in all such centers being directed when necessary to other agencies for medical, legal, and social guidance.

The clientele of these stations falls into three major categories: those seeking advice on premarital problems, those planning marriages, and concerned with uncertainties and difficulties related to child bearing in marriage, and those asking counsel on sex and other problems in and out of wedlock.

The greatest service of the agencies at present operating in the large and small cities of the United States, aside from their contribution to competent professional education in contraception, is that of preventive medicine in the field of venereal disease and pelvic cancer. Seventy of these stations for marriage advice are in 7 of the large cities: New York 25, Los Angeles 12, Chicago 10, San Francisco 9, Philadelphia 6, Cleveland 4, Cincinnati 4, 1 each in 20 cities in the East, 22 in mid-western cities, 9 in west coast cities and, 13 in southern cities.

There are in the United States at present 132 bureaus or agency activities devoted to some or all phases of marriage counselling, contributing directly toward better mental attitudes, avoidance of psychoses and neuroses arising out of maladjustment of ideas and ex-

periences before or during marriage. They also contribute to an honest, clean, and competent knowledge by husbands and wives of technics, procedures, and materials by the use of which choice as to the occurrence and intervals of pregnancy may be exercised, and the mother and family be spared some threatened invalidism. Twenty of these are operated by departments of public health; 25 are in hospitals; 12 do not wish their addresses made public.

European practice provides not only for official sanction but for attendance and service of representatives of three professions, the medical, the legal, and that of social work, each of which has been found necessary to meet the complexes of needs, fears, hopes, and catastrophes which are brought by the voluntary applicants for advice and assistance. Whatever may be one's intuitive, traditional, social, religious, or medical preference in the use of contraceptive information as a proper application of knowledge for the protection and integrity of the family, and to reduce the evidence of inherited and congenital disease and defect, the almost universal familiarity with half-truths on this subject, and the evident effect of their wide application in the falling birth rate make it incumbent upon physicians and health officers to familiarize themselves with organized efforts in this direction at home and abroad.

Furthermore, it would seem to me that rather than allow a disorderly, amateur, and more or less irresponsible development of marriage advice stations to grow, as is the present tendency in the United States, outside of official or organized professional control, it would be well for health officers to confer with the hospitals, medical schools, out-patient and social agencies of their communities to the end that a collaboration of these elements may come about without violence to the susceptibilities

of any church or social group which may hesitate as yet to lend its influence and approval.

There is no more suitable public agency than a hospital or a health department through which the combined services of medicine and social science can be made available to that portion of the public which cannot obtain, through professional channels of independent choice, the information and advice they need.

This is not a matter of choice to be determined by liberal or conservative attitude of mind, nor yet one to be settled on the basis of religious belief, but a question of exact information as to a way of life and adjustment between partners in marriage which is possessed primarily by persons trained in the biological and medical sciences. Preventive medicine of the kind every competent physician is daily concerned with includes advice prior to and during marriage, upon which physical, mental, and emotional health in the home may well depend. So far as preventive medicine is concerned, to be effective otherwise than through the private practitioner of medicine, it will in all probability be practised through the hospitals and health departments. I believe that a suitable outgrowth of the prenatal clinic or conference, and of the baby station as at present conducted by official and volunteer health agencies will be a marriage advice office or conference for men and women, single and married. For our needs at present in this country a physician, nurse, and social worker especially prepared for such a responsibility will be required at each such station.

Both mental hygiene and social hygiene, as these terms are used in our countries, should benefit by the official inclusion of a marriage advice service under the health department or in connection with the outpatient service of a general hospital.

This innovation will require some social initiative, imagination, and courage, in all of which it should be expected that the health officer should share or actually lead.

ALCOHOL

And now for another challenge for the social courage of health workers. Twenty years ago the health department of the City of New York availed itself of its good standing in the community to call to the attention of the public that among the frequent causes of death and disease was the beverage use of alcohol. The pamphlets issued at that time and the abstracts of scientific contributions on the subject were well received, widely copied and quoted. The declaration of public policy formulated in February, 1916, seems appropriate to quote here.

THE HEALTH DEPARTMENT'S ATTITUDE TOWARDS ALCOHOL

On June 29, 1915, at the request of Dr. Goldwater, then the Commissioner of Health, a committee of leading physicians, actuaries, educators, publicists, and others interested in the alcohol question, met to advise with the officers of the health department as to the most effective method of preventing such disease as alcohol causes or to which it contributes.

The opinions, expressed by the committee and the information in the hands of the department of health, as to the part played by alcohol in causing sickness and death, justified the entrance of the Department of Health into a field previously occupied chiefly by moralists rather than physicians.

Just as the control of venereal disease is a technical matter rather than a question of individual or community morals, so the knowledge of the serious effects of the use of alcohol is to be spread by education. As a measure of personal health and public preparedness against preventable disease and disability, this question should be approached from the medical and social point of view and not from that of morality and religion.

Admitting that the drunkard is a social misfit, our interest is rather with those users of alcohol who do not become irresponsible or guilty of antisocial acts. Such individuals are almost always ignorant of the fact that

alcohol decreases resistance to infectious diseases, such as tuberculosis and pneumonia. Alcohol is a depressant and not a stimulant; it drugs the brain and drops the capacity of the nervous system to obey the will. In this way the use of alcohol becomes an important factor in industrial accidents. Entirely aside from its action as a contributory cause in infectious diseases and industrial accidents, the intemperate or continued use of alcohol causes well recognized degenerative diseases.

The Department of Health has no sympathy with and will take no part in legislative or police restrictions or attempts to limit personal liberty in the use of alcoholic beverages. The spread of accurate information among the people as to the effects of alcohol can be depended upon to accomplish more than laws restricting its manufacture or sale.

In the long run, compulsory prohibition will not prohibit until the public is ready to cease using alcohol, at which time restrictive laws will be superfluous.—*Weekly Bull.*, New York City Health Dept., Feb. 19, 1916.

In view of the events of the past 15 years in the United States there is something almost prophetic in this official statement of 18 years ago.

At the Washington meeting of the American Public Health Association in 1917 and at the Cincinnati meeting in 1926 I ventured to present what I believed to be some of the reasons why the beverage use of alcohol should be considered a major problem of public health. In this opinion I had the support of that great educator, President Eliot of Harvard, and such authorities as Sir Arthur Newsholme and Sir George Newman of England. For these and other perhaps more compelling reasons of evidence and conviction I take this third opportunity to emphasize the importance of a rational scientific attitude toward the use of alcoholic drinks which I believe should be formulated and expressed by the official health agencies of this country. This appears to me of particular importance at this time, now that we have passed through more than a decade of political chicanery in attempts to enforce national prohibition, venal misconstruc-

tion of fact in the public press, and a debauching of governments by the liquor interests, and have returned to practically unlimited accessibility of alcohol of all strengths to all persons willing and with the money to buy. May I further emphasize the advisability of having any attitude or formulation of public policy, or efforts to educate the general public, in the actual and potential dangers of beverage alcohol, established by public and official rather than by volunteer or private health agencies.

It is not that I would draw a distinction between the Women's Christian Temperance Union or the Anti-Saloon League and the educational obligations of health departments; but rather to call your attention to the non-performance, the paralysis of interest, the consistent and well sustained aphasia of every national health agency on the subject of alcohol from the date of passage of the Eighteenth Amendment. The public of the United States cannot trust its nonofficial health agencies to guide them in the implications of alcohol as a cause of preventable disease and death in the face of powerful commercial selfishness, or when a particular health topic runs counter to the advertising interests of the public press.

It must be recalled that no one of the always influential and usually generously supported volunteer agencies composing the National Health Council has uttered a word of warning, contributed any substantial information or advice as to health implications of alcohol use, or published a report of new facts and observations of a scientific nature on the subject of beverage alcohol or its effect on human life, since 1920.

Even though the public pronouncements and presidential addresses of the American Social Hygiene Association had, prior to federal prohibition, on

occasion declared the well known and intimate causal or contributory rôle of alcohol in the development of venereal infection through commercialized prostitution, no suggestion has appeared from this association in the past 10 years and more, that there is any special hazard to youth in its recreation or pastimes from the use of alcohol, and yet in this period there was the most flagrant abuse of law and a widespread return of casual and clandestine immorality, developed and encouraged largely by illegal sale of liquor.

Also, the National Committee for Mental Hygiene suddenly became silent on the subject of the damage of this selective brain poison to human mentality, emotions, and behavior, and as a cause of functional nervous and psychic disorders, even though the great and technical leader of the mental hygiene movement, Dr. Thomas Salmon, had publicly declared that all the other mental disorders combined, as found among drivers of automobiles, did not equal in frequency or significance those caused by the use of alcohol. The national health agency which has preempted the field of preventable, toxic, hereditary, and infectious mental disorders for its own, has given no sign of awareness that alcohol was the cause of from 4 to 10 per cent of all new admissions to state hospitals for mental disease, such incidence varying with the alcohol consumption of various racial and economic groups. Certainly the fear of unpopularity acted as a depressant and inhibitor of the will-to-do in this agency, much as the drug alcohol does in the individual.

And again the National Tuberculosis Association, concerned necessarily with the economic and nutritional hazards of the wage earner and his family, as these affect the incidence or activity of tuberculous infection, has failed to make any single contribution to public education on the hazards of alcohol as an article

of diet for old or young, since the daily press turned thumbs-down on sumptuary legislation and encouraged the use of their columns for the deceptive publicity of liquor dealers, and for the encouragement of liquor users.

And lastly the American Child Health Association joined its sister societies in a common silence, not even raising its voice when legalized beer was again temptingly spread upon the advertising pages of our daily press as a sovereign remedy, a wholesome food for nursing mothers, and a suitable daily ration for children of any age. One almost looked expectantly for some word of praise of the rum ration said to have saved the lives of Canada's most recent quintuplets.

These national health agencies always had money for more and better central organization, for the public self-esteem that precedes the annual fund raising, but never a penny to pay for teaching the medical facts about the most widely used, but most harmful drug included in the dietary of modern occidental peoples.

Plainly, if and when conviction that alcohol constitutes a health hazard, more directly under man's own control to prevent than any other of equal significance, and determination to describe its effects in terms of sickness and death, are arrived at among professional health workers, it must be to public health officers supported by the tax payers, not private agencies sensitive to the wishes of a subscribing clientele that we must look for initiative and courage.

What Schmiedeberg and Kraepelin taught in 1883, what Cushny and Bastedo have written and described since 1900, what Benedict, Dodge and Miles have disclosed with exquisite experimental exactness in the past decade will be found accurately written in Emil Bogen's school book for the Department of Education of Los Angeles. It were

a pity that in this respect the public's physician, the health officer who speaks from the highest pulpit of health publicity, should linger still behind the knowledge of the school child in accurate unbiased information and opinion.

Here again if you have convictions bred of knowledge, then have courage to express yourselves for the public's sake. If you are uninformed in the matter, teachers of pharmacology and toxicology are available in every medical school in the land to enlighten you.

DIABETES

A further problem faces us, born it seems to me of the wealth, abundance, and transformation of man's life from one of bodily labor to that of command over machinery. I refer to that disease which has been for two score years and more increasing in incidence and mortality with astonishing uniformity among all classes of the population, in every state, and among both rural and urban dwellers. I refer to diabetes mellitus, recognized in the earliest records of Greek medicine, understood thoroughly on the basis of modern knowledge of body function and food uses, probably in the great mass of instances preventable, and yet to date not included within the concern of any health department except in the form of controversial statistics.

The small fraction of cases of diabetes which can reasonably be attributed to hereditary defect of the structure or function of the pancreas is probably on the increase, owing to the skill of physicians and the discoveries of laboratory workers who save the child diabetic to survive into parenthood, and carry an adult diabetic through the years of procreation, and yet we have no sufficient justification for interfering by law or persuasion with the marriage and child-bearing of those with this inherent defect. There remains the vast

majority of adult diabetics whose manner of life is the major if not the only factor in the development of the disease. The obese, the sedentary, persons of the later decades of life who by occupation and inclination avoid so far as possible, even in their amusement, and games, such exercise of the great mass of body muscles as in the past was necessary for almost anyone, these are the victims of a way of life in which appetite and easy access to abundance in variety and amount of food, and but slight necessity for bodily exertion, are the rule.

As I conceive it this disease is the expression of a change which has been gradual over a hundred years, but is now among us of extreme degree, when man's circumstance is considered before and since the industrial revolution of 1830. Almost every occupation has been metamorphosed by the accessibility of power so that even the daily chores of the home carry no physical burden. White-collar folks, masters of ships or industries, the professions, those who wait and serve food and drink, the employer rather than the employed, the financier rather than the ultimate producer of goods, these are the chief contributors to diabetes mortality, while the agriculturist, the lumberman, the sailor, the smelter and founder, the soldier, cattleman, the day laborer show everywhere a relatively low incidence of the disease.

In some the answer is mere gluttony, not different in nature from the excess expression of any body appetite. In the main bulk of cases however, the problem is one unrecognized by the average man and woman, namely, an imbalance between the body need for fuel to meet the ordinary demands of energy, heat, growth, and repair, and the use of food as tempted by opportunity and supply.

Of course, any disease which selectively prevails among those of the later decades of life will exhibit an increase

with the effective lengthening of life expectancy. Also a city or state with preponderance of those races which tend to engage only in trades or occupations free from much bodily exertion, such as the Jews, will show an increase in diabetes, but it is not race or changing age distribution alone that will account for the rise of diabetes mortality each year to new levels. Nor will the newer skills of diagnosis and treatment, or arbitrary procedures of registration practice explain the entry of diabetes well up among the first 10 causes of death in considerable urban population groups in this country. Diabetes rises with wealth, with command of mechanical power and convenience, with each advance to what some will hail as a bodily millenium, when no one sweats for his livelihood, no one walks to work, and recreation is achieved by exercise only of the little muscles of the eye and ear and fingers.

It is my present belief that health authorities should not only analyze the situation with epidemiological exactness, but issue warnings particularly to persons in the ages and occupations where diabetics are mostly bred, that they must adjust themselves to the mechanistic motorized era by both moderating their own fuel intake and by increasing the physical employment of their great body muscles in work or play.

This is a challenge in the field of hygiene which demands critical approach, and a certain courage in public speech and education, because what seems to me to be the needed word of advice runs counter to man's tendency ever to cherish his indolence, and to delight in lethargy after surfeit.

OCCUPATIONAL DISEASE

I would persuade you to seize and occupy the largest field of preventive medicine, until now excluded from the work of official health organizations in this country. I refer to the prevention

of occupational disease. There has been no greater prophet in the history of medicine than that great clinician and keen epidemiologist Bernardini Ramazzini, who laid the foundation for the study and prevention of diseases of artificers in 1717. One of man's distinctions from the brutes is in his use of tools. With tools and trades came contact with other materials, other environments than the comfortable wholesomeness which the herder, the farmer, and the woodsman knew.

In the finest flowering of a liberal civilization when Italy gave to Europe cities of wealth and culture, Ramazzini detected those beginnings of special hazard among clerks from sitting all day at desks, of those who stood at their work, or delved in mines or handled metals or chemicals. Long before the industrial revolution of 1830 transformed the life of man into one of shop and factory, an obligation was imposed upon sanitarians to protect the workman against ill health and premature death lurking in the very nature of his livelihood.

Organized labor has fought to guard the interests of workmen by compensation for employer's neglect and the unwitting risks of dangerous trades, for accidents and poisonings, but the approach, the benefits, the influence toward betterment has been chiefly through financial pressure on the insurance principle.

Great progress has been made in learning the nature of the physical and psychological damage due to the material and emotional handicaps of a multitude of employments. Great Britain, Germany, most European countries, and many of our states have created official agencies to protect the body and the pocketbook of the working man and woman; and yet, at least with us, only the very fringe of the matter has been touched; hardly more than a beginning has been made, and practically nothing

has been done by departments of health in industrial hygiene. It is true that the self-interest of employers in the larger and well organized industries has brought important tangible improvements by physical safeguards and through the employment of physicians and engineers skilled in abating industrial hazards. Also it is true that the U. S. Public Health Service has accepted the serious responsibility of studying the effects of particular trades and occupations upon the current and subsequent health of workmen. But that is not enough. In addition to workmen's compensation laws, and besides the authority of factory inspection, and to supplement the contribution of industry itself and of the federal government, it should be the acknowledged duty of each department of health of whatever population group from rural county to tightly packed industrial state, to concern itself with every variety of occupational handicap to health, and provide through environmental inspection, through medical examination, and by the technical skills of the laboratory a service in some measure comparable with present control of communicable disease.

It is, as Dr. Osler said, the tragedy of today that man is so indifferent to the life of man. Yes, we surround the babe unborn with premonitory protection, deal wisely and gently with infancy and childhood, and then hurl the product of a reasonably healthy youth into a maelstrom of blind chances, of dusts, fumes and fatigues which wear down the stoutest body and cripple the most willing worker.

Ours is a day of increasing mechanization of infinite complexity, of new chemistry and physics, and of occupations calling for hardly more than the spirit of a Robot.

If we would be true to our own generation, and in our day contribute as the bacteriologists did first 50 years

ago, and as the nutritionists have done in recent decades, we must use our powers of education, of information, of inspection and abatement, to make all employment as nearly compatible with health as our knowledge permits. Let us have the courage to create a division, an office, a sphere of influence in every health department to be concerned with occupational disease.

VOLUNTEER HEALTH AGENCIES

May I venture one further, and my last suggestion calling for a measure of social courage for the sake of public health? This I address chiefly to the generous lay public which supports private health agencies, both national and local. It has been my observation that where there is high quality of professional leadership and reasonably adequate support for the department of health, private health agencies do not multiply or increase in importance. The visiting nurse associations are in my opinion the only volunteer health agencies still indispensable where a community has a well organized health department. This leads to the further opinion that if the time, effort, organizing ability, public spirit, and contributions in cash for volunteer health agencies were diverted to the direct and exclusive support and advancement of the health department, almost any community would be better served than at present, with less cost, less confusion, less rivalry for public credit, and more community self-respect. Protection of the public health, as distinct from the private practise of preventive medicine, is a highly responsible technical and complicated function properly vested in civil government and trusted to professionally trained health officers. In an orderly and mature society the amateur, the volunteer, has no proper place as an agent of public health in a city, county, or other local political unit.

If we have the determination which

I believe we should have to make our form of government an efficient instrument of social progress, we can no longer afford to have an amateur as well as an official government in each community, one run by public spirit'd well wishers, the other by electe' officers and their appointees.

The good people who support a duplication of governmental functions in health, welfare, and education will do well to attack community needs at the source, and see to it that the health department at least does those things, and does them superlatively well, which philanthropy and executives responsible to volunteer boards can achieve only fractionally under private auspices. It is full time for us to declare our civic independence of amateur health service as we long ago gave over the police and fire departments to local government.

In the present stage of development of civil government I do not see clearly an entirely safe way by which the health and sickness services of the public health and visiting nurses can be absorbed by either the department of health or by any other branch of local government, but as for all other variety of nonofficial local health agencies, distinct from social and relief or family welfare organizations, I believe their discontinuance, with a transfer of interest and support to the health department, would result in a real advance in government in the United States and in the direction of effective non-political health service.

There may still be for a while longer a place for nonofficial national health agencies under some form of central relationship which will permit each such nation-wide organization, devoted to a particular health function, to operate as a bureau of the single central body, thus maintaining a reasonable sense of relative importance in the several fields of health promotion and education.

It should be the declared hope and prospect of this body of professional health workers to encourage the replacement of voluntary by official responsibility for all useful public health functions under government authority. The institutions of professional education and those of scientific research need no other field for demonstration and test of new procedures than the population groups served by agents of civil government. Only by consent of local official health authority can any population unit be used by a private health agency for exposition of some new procedure. As a matter of record I believe it is true that no public health procedure of certain merit has been proposed or applied under private auspices that had not already been applied and made effective by an officer of a governmental health agency.

The local private health agency has served its once useful purpose, as did the Vigilantes and the Stalwarts for suppression of violence and assistance in control of fires, and they should be gently but firmly eased out of the picture while professional official leadership assumes full control of the situation.

SUMMARY

And now, good friends, forgive me if I have not the gift of simplicity and clarity of a Chapin, nor the practical wisdom of a Vaughan, father or son, nor the persuasive logic of a Park, and let me briefly summarize my thesis so that at least some kernel of my thought you may carry off, perhaps to consider, possibly to cast aside as of little merit, but I hope in some measure to test in action and prove in practice.

We are in a position to raise a little the level, and to extend the application of human intelligence. It is our duty to be so faithful to the scientific method, so loyal to the truth, that our authority will be everywhere accepted. To com-

promise with truth for the sake of popularity and publicity hazards the credit of our profession.

It is unlikely that we shall possess such wealth that all can at the same time have the indulgences and the enduring satisfactions or securities of life. Some self-denial, some individual sacrifice of unessentials appear to me to be prior requisites for our investment as liberally in the application of natural sciences to human nature as we know would be both wise and profitable.

A combination of thriftiness, shrewd intelligence, and devotion akin to that of religious crusaders is called for. We who have the knowledge and the vision must teach by example as well as by precept. Five unessentials, the use of which we can if we will reduce, to permit a liberal expenditure for health, are alcohol, tobacco, tea, coffee, and cosmetics.

Then as to social courage for which further advance in public health awaits rather than for more knowledge, wealth or authority:

Let us complete the job of raising man out of the health hazards of his own bodily filth.

Let us directly in the manner of sanitarians and physicians attack syphilis.

Let us acknowledge the evidence of the medical sciences that ethyl alcohol as commonly used for a beverage is a drag on the health and happiness of man, and let us deal with it as a drug

and a poison without the pretense of its being a necessity or a blessing.

Let us teach for the sake of women the knowledge which will permit them to choose the time and circumstance of their own childbearing.

Let us recognize the new health problem of diabetes, a disorder of metabolism which has grown with increased command of foods and the power of mechanics, permitting man's escape from physical drudgery, and teach such adjustment in nutrition and muscular activity as experience indicates.

Let us incorporate within the permanent functions of health departments, protection of employed persons against health handicaps inherent in the place and nature of their work.

Let us build upon the permanent structure of official health services under civil government and divert toward this the public spirit and support, until now applied to local nonofficial health promotion, excepting always the visiting nurse.

Health such as modern man and his family can command awaits not more knowledge, but imagination in the use of what we have, in professional leadership, and social courage to follow and support the leaders. By the quality of your guidance, the future of human life among the four nations professionally represented here will be determined in the decades immediately before us.

The TVA's New Deal in Health*

E. L. BISHOP, M.D., F.A.P.H.A. (*Life Member*)

Director of Health, Tennessee Valley Authority, Knoxville, Tenn.

THE Tennessee River and its tributaries drain an area of more than 40,000 square miles, extending from Virginia and Western North Carolina through Eastern Tennessee, south and west through Georgia, Alabama, Mississippi, back north through Western Tennessee and across the corner of Kentucky with almost ideally situated areas for storage basins. From its head waters the river falls rapidly to provide excellent power sites at other points in its course. Rich in a multitude of minerals, the drainage basin affords also the possibility of broadly diversified agriculture through its mountainous sections, uplands, and broad valleys. Climatically, its situation is almost ideal, with long growing seasons, adequate rainfalls, and mild winters. More than 2,000,000 people of as fine a native stock as may be found in the nation reside within its boundaries.

In this area are the materials both of natural and vital resources from which, through effective combination, an almost ideal condition of life may be wrought; for there are raw materials of wide variety, potential power in ample quantity, and the human resources essential in effecting a reaction of one upon the other for the creation of usable wealth.

The bringing together of these elements into one coördinated development

is, however, a major problem of organization not possible of solution except through long range planning and unity of approach. It must be remembered in this connection that the drainage basin, though naturally a unit in itself, extends into seven separate states. The unusual richness of resources and the crying need of their development, together with the complexities of the organization problem must have been in President Roosevelt's mind when he expressed his idea of a long range planning in a message to Congress asking creation of the Tennessee Valley Authority. He said, in part:

I, therefore, suggest to the Congress, legislation to create a Tennessee Valley Authority—a corporation clothed with the powers (limited) of government but possessed of the flexibility and initiative of a private enterprise. It should be charged with the broadest duty of planning for the proper use, conservation, and development of the natural resources of the Tennessee River drainage basin and its adjoining territory for the general, social and economic welfare of the nation. This authority should be clothed, also, with the necessary power to carry these plans into effect. Its duty should be the rehabilitation of the Muscle Shoals development and the coördination of it with the wider plan.

Many hard lessons have taught us the human waste that results from lack of planning. Here and there a few wise cities and counties have looked ahead and planned. But our nation has "just grown." It is time to extend planning to a wider field, in this instance comprehending in one great project many states directly concerned with the basin of one of our greatest rivers.

A little more than a year ago the three directors of the Tennessee Valley

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 4, 1934.

Authority held their first meeting in a Washington hotel. Since that time more than 100 similar meetings have been held, and nearly 10,000 workers are busily employed in bringing to realization a masterly vision. The Wilson Dam, instead of standing idle, is busily engaged in turning out electrical energy. The Wheeler Dam, 15 miles above Wilson, is approximately one-quarter complete, as is also the Norris Dam, located on the Clinch River, one of the principal tributaries of the Tennessee. Projected for the future are two more storage dams and two run-of-the-river dams. Thus, will come power for the transmutation of raw products through human agencies into usable wealth.

Naturally in view of the rich agricultural possibilities of the basin, agriculture and soil conservation through the prevention of soil erosion, afforestation and soil feeding are receiving their due measure of attention. Indeed, the Tennessee Valley Authority law provides for research in fertilizer manufacture and for the manufacture of fertilizer ingredients whenever it seems wise. With all this attention to natural resources and the production of power, the Authority is not unmindful of the part which the conservation of human resources must play in the realization of its program, for natural resources are practically valueless without human resources. It is, therefore, assuming the rôle of an enlightened employer toward its employees and of a constructive force in the protection and conservation of health. No attempt is being, or will be, made to develop a separate health agency, but rather the purpose is to support, strengthen and develop existing agencies in so far as this seems necessary and desirable.

All activity of this nature is centered in a section of Medical Service and Health, which is located in the Division of Personnel, one of the service divisions.

The primary objectives of the Medical Service are physical examination and classification according to physical status of all applicants for employment; direct medical care for all employees injured in line of duty until responsibility is assumed by the Federal Compensation Commission; emergency medical care for employees away from their natural residence; assistance in the proper placement of employees with physical handicaps; immunization service for all employees; the control of venereal diseases through a familial approach including prophylaxis, treatment, and education of the employee and his family. In addition, this service assumes responsibility for the compilation and clearing of all compensation claims originating from employees of the Authority.

Because of the wide separation of areas for which service is essential, centers have been established at each site of major activity, including the town construction area at Norris, the site of the Norris Dam, the base of the Norris Reservoir Clearance operation, the site of the Wheeler Dam, the Muscle Shoals area, and the base of the Wheeler Reservoir Clearance Area. Each area is under the direction of a medical officer, to whom is assigned essential subordinate personnel.

After physical examination and prior to final employment, prospective employees are classified into four groups according to physical fitness for duty, then given essential immunization and assigned by the personnel director to service. All injuries, even such as appear insignificant, are given immediate first aid and passed on as quickly as possible by a physician at one of the first aid infirmaries. In the opinion of the Director of the Safety Section, the low degree of severity of injuries is in a large measure attributable to thorough physical examination and prompt medical attention to injuries.

While as yet no systematic activity to secure correction of observed physical deficiency has been established because of the pressure of more immediate responsibilities, it is the observation of the field medical officers that corrections are being made in considerable numbers. A more specific approach to this problem is contemplated as early as possible with the available resources.

The problem of health and sanitation service necessarily includes not only such activity as is necessary within areas directly under the jurisdiction of the Authority and having essentially the status of government reservations, but also, through coöperative agreement, this same activity may be extended to areas immediately adjacent so that conditions reacting upon the health and welfare of employees may be dealt with as those occurring within the area. The administration of service within areas directly under the jurisdiction of the Authority is simple and is directed by our own medical officers and engineers. The organization of service outside of such areas must depend upon coöperative agreements with state and local health authorities, since this is their responsibility. Hence, a small fund has been set aside to become available for strengthening local health services in the major areas of operations, where the activity of the Authority complicates local conditions or where local conditions are such as to result in undue hazard to employees. In two major areas of operations, for example, typhoid epidemics—approximately 100 cases in one instance and 40 cases in the other—have indicated not only the desirability, but the actual necessity of coöperation from the Authority.

Questions of food and milk control, general sanitation, and the usual public health services, it is believed can be solved in regard to the safety of employees by strengthening rather than duplicating existing facilities.

Unquestionably, as a result of the vastly increased shore-line of impounded waters within the drainage basin, malaria will become one of the outstanding problems of the future. Here the same long-range planning, characteristic of the vision of the Authority for the project as a whole, is manifest, for this matter has had serious consideration from the time the dams now in process of construction were designed, and provision has been made for such fluctuations of reservoir levels as are essential to a maximum degree of biological control. Some idea of the extent of this problem may be had from the fact that the Norris Lake will have a shore-line of approximately 800 miles, Lake Wheeler a shore-line of approximately 800 miles, making a total of 1,600 miles. Compared with the present shore-line of Lake Wilson, which covers only 125 miles, the tremendous increase in the extent of this problem is apparent immediately.

Not only does malaria offer an additional example of the need for long-range planning, but also an illustration of the desirability of coöperation with state and local health agencies in the development of strong local health services in the areas affected. A first line of defense is an effective local health organization for each county, contiguous to the impounded areas. Coöperative agreements are in process of negotiation with state and local health authorities and will result undoubtedly in more effective and less costly procedures than if an attempt were made to solve the problem unassisted.

In addition to the need for coöperative development of control services, both the opportunity and necessity for special researches are apparent. For example, we need more precise knowledge of our malaria problem and more effective methods for its control. It is desirable that we should investigate the possibility of improving many of our

public health measures and study our administrative procedures.

Through and with the coöperation of existing agencies, material advances in the acquisition of new knowledge and methods of applying existing knowledge should be possible. With these facts in mind, provision has been made for such basic studies both in epidemiological and administrative procedures as now seem desirable for the development of improved methods in dealing with problems incident to or produced by operations of the Authority. Such studies may include analysis and evaluation of needs of rural areas, the development of the most effective and economical methods for meeting these needs; determination of the type of local health organizations capable of putting such methods into effect, and the acquisition of such new knowledge of conditions under which diseases occur, as may be possible.

Plans now being made for the study of malaria will illustrate the care with which these studies are being approached. Almost immediately a study of the possibility of applying airplane dusting to a shore-line, such as we shall have, will be developed. Previous studies have been made of acreage dusting by airplane, but no satisfactory investigation of shore-line dusting is available.

The procedure being followed in developing personnel for studies and control service is of interest. Through the coöperation of one of the foundations, an unusually capable medical officer is being trained in malariology in order that all malaria studies and control service may be directed by a competent person. More than a year of special studies under the best malariologists of the world will be given this officer during his training. Engineering service for malaria studies and control has already been provided. An individual trained in certain of the natural sciences

is contemplated as a possible third element in this work, thus balancing the personnel group and making possible accurate measurements of mosquito and parasite indices, together with special surveys and investigations essential to a definition of the control problem.

Malaria is used as an example of the type of research and method of approach. Unquestionably, the need will arise for investigation of other approaches. Other studies which may afford a basis of future guidance are appropriate administrative units of population; definition of the nature and extent of prevailing health problems; studies of personnel requirements, unit costs, and personnel performance; and field studies of both the epidemiological and survey types.

Nearly all prior studies of rural health service and rural health projects, especially of an administrative nature, have been of a more or less negative character for the reason that they have had inadequate fields of study, or provision has been made for too brief periods of time. Thus, in many such studies the observations have been of deficiencies rather than of positive performance, and conclusions have been reached by inference rather than by logical analysis. It is believed that these difficulties can be avoided in our procedure, and that positive observations rather than negative inferences may become possible.

A *sine qua non* for any scientific study is personnel of high quality and expert training. The policy of the Authority for selection of its employees is admirably epitomized by the Chairman, Dr. A. E. Morgan, in three brief sentences:

There is a provision that no political test of any kind shall enter in the employment of men on this Tennessee Valley Authority work. Men shall be employed on the basis of merit and no other. The TVA is working in that spirit.

The staff of the Health and Medical Sections is composed, therefore, of unusually capable and well trained individuals. This fact is sufficient evidence of careful planning and a forward-looking policy.

In development of the entire health program, the method of approach will be through and with the coöperation of existing health agencies—federal, state, and local—to the fullest possible extent. For example, the central administrative service of the section includes, as the associate director of the section as a whole, one of the officers of the U. S. Public Health Service, together with a Regional Consultant in county health work, and a sanitary engineer from the same organization. Thus, coöperation is established immediately with the principal federal health agency, and complete coördination is effected. Approach to any local health agency is through the state health organization, and all activity in a given state has as a minimum basis the regulations and policy of that state. In this way, not only is interference and duplication prevented, but also there is actual strengthening of both the existing health agency and the program of the Authority. The wisdom of the policy is illustrated by the fact that not a single major disagreement has arisen with any existing

health agency, despite the rapid growth in organization and activity.

In conclusion, and in illustration of the rapidity with which the activity of the sections has been developed, the growth of the staff may be cited. When this Association held its last meeting, the staff of the section consisted of one individual, the director. Its present budget, exclusive of all coöperative and special studies personnel, consists of 21 medical officers, 3 sanitary engineers, 9 semi-professional persons, and 35 clerical and other employees, or a total staff of 68.

It should be apparent, therefore, that the Authority recognizes the conservation of vital resources as a part of the foundation upon which both social and economic well-being must rest. Indeed, the very language of its basic Act implies this recognition by reference to the "orderly and proper physical, economic, and social development of said areas" and "such studies, experiments, and demonstrations as may be necessary and suitable to that end."

If the Authority, as a collateral result of activity in carrying out its direct and specific responsibility, demonstrates that a reduction in the wastage of vital resources is an economic possibility, then we shall have additional evidence of the value of conserving these resources.

Vitamin D Studies, 1933-1934

E. C. McBEATH, M.D., D.D.S.

Associate Professor of Dentistry, Columbia University, New York, N. Y.

THESE studies comprise the administration of vitamin D (cod liver oil vitamin D concentrate—Zucker process, 1933) in evaporated milk and dairy milk, in varied unitages; also ultra-violet irradiation of the skin.

The children included in the control and experimental groups numbered about 425, boys and girls, aged 8 to 14 years, at four institutions in and near New York City. The institutions are orphanages and are the permanent homes of the children studied. Two of these institutions are conducted on the cottage plan, thereby making it possible to segregate the children for control and experimental management. Each cottage represents a separate group. In the other homes segregation of the study groups was maintained by rigid discipline and a daily program which provided for the time and place of these administrations.

Controls were run as follows: In each institution one group continued on its regular diet and one group received a specified amount of plain evaporated milk (no extra vitamin D). These were the negative controls. The number chosen was large enough so that if the results were negative, or near negative, the number of control observations would be sufficient and so distributed that a maximum of clarity in the results would be obtained. Since in the past irradiation with ultra-violet lamp has given such apparently striking results for several years in succession,

an irradiated group was included to act in a sense as a positive control.

The experimental groups were given vitamin D milk at three different levels of vitamin D. In a pint of reconstituted milk the following levels were given:

100 units daily

150 " "

300 " "

Last year about 150 units daily of vitamin D in fresh milk was given with apparently definite results which, however, were quantitatively not so good as the results with irradiation. In this year's study several groups on 300 units were included to ascertain whether last year's results were due to insufficient dosage. If vitamin D is a large factor in determining the caries incidence, the spacing of 100, 150, and 300 units per day would show either a graduation or else it must probably be concluded that a larger dose is not more beneficial. If vitamin D is not a large factor in caries, or the distribution of caries in children of this age is too irregular to be subject to such observations as were made here, the facts ought to come out clearly due to the large number and distribution of the controls.

However, the groups were also large enough so that if there was a positive result from vitamin D administration, the three levels would give valuable information. Based on previous experience, the three levels were so distributed that they would show a slight, moderate, and rather marked effect. It was

thought better not to attempt this year to evaluate the possible maximum effect but first to verify the indications of previous years.

To make the milk consumption least burdensome for those children who are not fond of milk, and to secure the best results in regularity of intake, the milk (except the fresh milk furnished by the dairy) was slightly flavored with chocolate. Each milk was repeatedly assayed and found to be of the stated potency well within the limit of error to the method.

The unitage given is in the Steenbock units as described in *New and Non-official Remedies*.

Dental examinations of these chil-

dren were made in November, 1933, February, 1934, and the latter part of April, 1934. All three examinations were made and recorded by the same persons during the entire study. The total number of carious tooth surfaces in each mouth at each examination was recorded as the percentage of the total number of tooth surfaces present in each mouth. The differences in these totals indicate the increases in carious surfaces at the end of each period. The differences in the percentage increases indicate the progress of dental caries during the year of study.

The three dental examinations of the year yielded the findings shown in Table I.

CONCLUSIONS

1. There is possible a nutritional control of dental caries.
2. Vitamin D is an important factor in the nutritional control of dental caries.
3. Clinical observations point to a probable correlation of the degree of

control of dental caries with the quantitative dosage of vitamin D.

NOTE: The data in the foregoing paper have been extensively analyzed statistically by Professor Earle B. Phelps Professor of Sanitary Engineering, Columbia University, New York, N. Y., and the results have been found significant.

Solution of the Streptococcus Carrier Problem^{*†}

C. W. BONYNGE, M.D.

*Director, Milk Commission of the Los Angeles County Medical Association,
Los Angeles, Calif.*

RESULTS of a 3 year program carried on for the exclusion of streptococcus carriers from the employees of a large dairy industry are presented, with especial reference to the clearing up under treatment of certain throat carriers of this organism.

Of the milk-borne diseases, streptococcal infections have proved the most disastrous, from the standpoints of the number of epidemics and of individuals involved. Septic sore throat has played a prominent rôle in this picture, as shown by Brooks¹ in reporting records of 72 epidemics up to 1932, with evidence of many having passed unrecorded.

In the light of our present knowledge, one must approach a discussion of the epidemiology of either scarlet fever or septic throat with caution; yet developments in the last decade would seem to justify the following conception regarding the latter disease.

While early investigators had reported a hemolytic streptococcus as the causative organism of septic sore throat, Davis² in his study of an extensive epidemic in 1912, was the first to describe what is now known as the *Streptococcus epidemicus*. He found

that this organism exhibited characteristics which distinguished it from the conventional *Streptococcus pyogenes*. Stock strains recovered from previous epidemics conformed to his description, and his findings have been confirmed by Brown, Frost, and Shaw,³ and others.

In view of the fact that probably, with a single exception, all outbreaks of septic sore throat have been traced to milk as their source, later studies by Davis⁴ were of great import since they led to the reasonable conclusion that the dairy cow was not the natural reservoir of *Streptococcus epidemicus* but became infected through contact with human carriers.

As a result of these developments, the American Association of Medical Milk Commissions in 1929 recommended cultural examinations of individual cows in certified herds for the detection of streptococcus carriers, and later advised that measures be taken for the exclusion of possible carriers among dairy employees.

In 1930, the Milk Commission of the Los Angeles County Medical Association adopted the above program to include both employees and animals.

We have employed the technic as outlined by Frost, Gumm, and Thomas,⁵ and amended by Pilot, Hallman, and Davis,⁶ with the exception of dry preparations with Pelikan ink No. 542 for capsule demonstration. We feel this method gives better results than the wet

† From Department of Experimental Medicine, University of Southern California Medical School.

preparations originally suggested and, in addition, affords permanent records. The addition of the ascitic fluid, as used in the amendment, is very valuable.

The Los Angeles Milk Commission certifies 4 dairies, maintaining more than 3,000 animals with about 250 employees. Monthly cultures of milk from the individual cows have been carried out for more than 4 years and during this period *S. epidemicus* has been found only twice, each time from animals imported from outside the state. Both were in the same dairy but came from different states. Neither animal showed gross evidence of mastitis though both were shedding enormous numbers of typical organisms. They were apparently in the carrier state and would have escaped detection except for the special cultural examinations. The subsequent elimination of these carriers from the herd removed a possible source of an outbreak of streptococcus infection among our consumers as both strains showed a high virulence for mice.

The results of our control program among the employees present an entirely different picture and possibly have some bearing on the low incidence of positives among the animals. Monthly throat cultures of the entire employee personnel, in addition to culture on entrance examination, have been carried out for 41 months. During this period approximately 1,000 employees have been examined, requiring around 12,000 cultures. Fifty of these men have been found to harbor streptococci typical of the Davis organism. An attempt to evaluate the percentage incidence of positives would not give accurate information for general use as the figures represent a single culture in some of the men and repeated cultures in the majority.

As previously reported,⁷ the original survey of the initial group of some 250

men showed a positive incidence of 2.8 per cent. However, 9 per cent positive cultures were found in a study of 66 individuals presenting themselves for tonsillectomy in one of our hospitals where cultures were made from the tonsillar crypts immediately after operation. Pilot, Hallman, and Davis⁸ reported similar findings and emphasized the difference of results according to the care with which cultures were obtained. Experience and care in the technic of taking the throat swabs may have some bearing on our relatively high positive findings of approximately 5 per cent.

All of our carriers gave negative histories of septic sore throat and none showed evidence of acute infection at the time of the positive culture, although some degree of hypertrophy of the tonsils was invariably present. Upon the discovery of the first group of carriers, we were much embarrassed over the responsibility of their disposal, since our health regulations did not recognize either septic sore throat or streptococcus carriers.

Summary discharge would have entailed unjust hardship on the employee and in some cases on the employer. It was also difficult to disregard the responsibility incurred had we released known carriers who might have passed on to uncontrolled raw milk dairies.

Another important factor was the interest shown by our 250 employees in our disposition of these cases, indicating that ultimate success in our program demanded that some effort be made to relieve carriers and restore them to usefulness. As tonsillectomy seemed to offer the only rational and permanent solution, we adopted this measure and met with such success that we have continued it since 1931, in spite of its difficulties and hazards.

Thirty-four, or 68 per cent, of the 50 carriers have been treated in this manner. Of the 16 carriers not operated

upon, the majority refused consent and the remainder were rejected as undesirable applicants for employment or poor physical risks. All cases not operated upon have been reported to the health authorities who have attempted to keep them from working in uncontrolled raw milk dairies.

We have been successful in clearing up the entire group submitting to operation, though not without some difficulty, especially in our earlier experience. Twenty-six, or 85 per cent of the cases were found negative for hemolytic streptococci on the first culture after convalescence and have remained so; 5 failed to give immediate results, the failures being due to incomplete tonsillectomy; to the retention of the organism in the lingual tonsil; or to lymphoid tissue at the base of tongue or in the pharynx. Removal of the tonsil tags and, where possible, the lymphoid tissue, usually brought prompt results; otherwise, local treatment usually with silver nitrate was employed. All of these cases were eventually cleared up.

One of the members of this group, an employee having no contact with cows or milk, was treated by topical applications of chemical germicides, bacteriophage, anti-virus, and even ultra-violet ray. After 3 months' trial without results, the man was returned to the surgeon and under the treatment mentioned became negative.

In the early part of the work, the men were operated upon in clinics or by surgeons of their own choice. This proved unsatisfactory, so arrangements were made to have all tonsillectomies performed by one surgeon familiar with the circumstances under which they were being done. Under this plan, our results have proved much more satisfactory, with few failures in the original operation and a minimum loss of time to the employee.

Apparently these carriers, when once properly cleaned up, remain so

permanently, as shown by monthly cultures. We have records of 6 men for over 3 years, and 8 for more than 2 years. In 1 case the cultures were negative until 4 months after the tonsillectomy, when the organism again appeared. Removal of a small residual mass of lymphoid tissue rendered his throat culture negative and it has continued so for 2 years. This is hardly to be considered an exception.

As to the permanency of the carrier state when once established, we found that 4 men who refused the initial operation and reapplied for employment after periods of 1, 4, 6, and 15 months, respectively, were still positive.

Naturally there comes to mind the question of difficulties encountered with the employees in carrying out a program of this type. Our first problem was the elimination of carriers found in the original group, and second, to prevent entrance of infected men among the numerous replacements. Needless to say, we are unable to force them to undergo operation, and care is taken in each case to impress upon them that the procedure is not compulsory except that otherwise they must retire from employment at certified dairies. They are also impressed with the fact that they must assume all responsibility, and care is taken that they present themselves voluntarily to the surgeon.

Written consent is not obtained as we have been advised this precaution is not a protection. Just how far our precautions protect us from legal responsibility is questionable. However, every possible care is taken of the patient and we feel that so far the end has justified the means. At the start, we encountered considerable difficulty in bringing the men to operation, but with each case successfully handled the morale has increased until at present they accept readily, and in some instances with a certain amount of gratitude our bringing about relief of diseased tonsils.

We have had no accidents or delayed convalescence. One of the first cases passed out of our control and after 2 weeks' delay was operated upon while suffering with an acute throat. He developed a severe postoperative streptococcal angina, complicated by extensive erysipelatous cervical cellulitis. For a time the outcome appeared doubtful but after convalescence of some 2 months, he returned to work and has been with us since. This experience gave us much concern and was one of the reasons we assumed control of the operations.

We wish to express our respect for the opinions of Anna Williams⁹ and others as to the close relationship of the streptococcus of Davis to the organism of scarlet fever. Our experience has been that at times it is difficult to differentiate them, and we admit that some of the strains rejected have possibly been those of scarlet fever. We also have been interested in the character of the so-called capsule of this group. However, in the study of some hundred separate strains recovered at large, we believe it to be a permanent and important characteristic.

So far as can be determined, septic sore throat has never appeared in our community in epidemic form though sporadic cases are occasionally seen which are clinically typical and exhibit the characteristic Davis organism. We have also found pure cultures of *S. epidemicus* in pus obtained from mastoiditis at operation. Of 5 strains of hemolytic streptococci recovered in blood cultures from cases of general sepsis clinically identical, 3 were typical epidemicus, 2 were classified as pyogenes.

SUMMARY AND CONCLUSIONS

Among a group of men required to maintain a personnel of 250 employees,

over a period of 3 years, 50 individuals were demonstrated to be throat carriers of *S. epidemicus*.

Thirty-four submitting to treatment were cleared of the organism and have remained negative under monthly cultural examination.

Among the animals required to maintain combined herds numbering around 3,000, for a period of 4 years, 2 were found with udders infected with *S. epidemicus* without gross evidence of mastitis.

In a community in which an epidemic has never been known, infection with the *S. epidemicus* exists endemically as clinical septic sore throat and extra angular infections, in addition to the carrier state.

Where the beta hemolytic streptococcus has become established in the oropharyngeal cavity, the organism may be found in all of the lymphoid tissues of this area.

This fact is to be borne in mind when tonsillectomy is advised for the relief of focalized throat infections.

Approval of Laboratories for Surgical Pathology in New York State*

AUGUSTUS WADSWORTH, M.D., F.A.P.H.A., AND RUTH GILBERT, M.D., F.A.P.H.A., (*Life Member*)

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

THE practitioner of medicine today, wherever he may be located—in a medical center or in a rural district—must have laboratory service. From a broad point of view, the administration of public health measures is primarily dependent upon the maintenance of modern standards in the practice of medicine at the bedside, and thus ultimately upon laboratory service. To be effective, laboratory facilities must be readily available and the work entirely dependable. Examinations can usually be performed most efficiently when undertaken promptly after the specimens have been collected. In many cases, also, if a capable laboratory director is so situated that he can see the patient with the attending physician, the best interests of all concerned will be furthered. Thus, the maintenance of adequate standards and decentralization in locally established laboratories, with a supporting supervision—as opposed to a centralized service by a state organization—become issues of primary importance.

Information concerning the manner in which these problems have been met in different parts of the country may be of interest. We are very grateful for the

responses which have been received to inquiries sent to various health departments. The replies have indicated that, in 25 states, arrangements for determining the efficiency of laboratory service have not as yet been made. In 14, supervision of certain phases of the work has been undertaken. The public health laws or other regulations in 5 of the latter group require certain of the diagnostic laboratories to receive official sanction for the conduct of some types of examination. In 2 of these, the technical personnel are provided with certificates showing the kinds of work which they have been found capable of performing. The data furnished thus indicate that the provision which has been made for laboratory service varies markedly in the different states and, for the most part, is limited in scope.

In New York State, the present system of laboratory service dates from the reorganization of the Department of Health approximately 20 years ago, following the revision of the Public Health Law and the appointment of the late Dr. Hermann M. Biggs as Commissioner. The Public Health Council was created at the time of this reorganization. It is without executive or administrative functions, but is authorized to enact a Sanitary Code dealing with any matters affecting the security of life or health in the state (exclusive of

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

the Greater City of New York) and having the force and effect of law. Plans were also inaugurated at that time to broaden the character and scope of the laboratories already serving a few districts and to encourage the establishment of additional ones—all in cooperation with and aided by the central laboratory in Albany—in order that all sections of the state might be provided with an adequate service.¹⁻⁴

The first survey of the laboratories in the state was made in 1915. The ability of the directors and the standards of work varied widely. Thirty-six certificates of approval for a few types of tests for evidence of communicable disease were issued that year to laboratories in which the character of the work warranted such recognition and whose directors were interested in the project. Gradually, more procedures were included and the minimum standards raised. For many years, certain districts, particularly those composed of rural communities, were without easily accessible, adequate laboratory service. This situation was markedly improved in 1923 by the passage of a law granting financial aid from the state, by which under certain conditions it became possible for counties or cities which could not otherwise support an efficient laboratory to equip and maintain one or more.

The number of approved laboratories increased from year to year until in 1934 it has reached 184—129 in which diagnostic service is rendered and 55 in which milk or water examinations only are made. The New York State Association of Public Health Laboratories, formed in 1916, has gradually become an important factor in advancing the standards of laboratory service. It is composed of persons in charge of approved laboratories and those of their assistants who have had adequate training and experience to represent the laboratory. Meetings are held semi-

annually, at which results of experimental work are reported and topics of general interest discussed; cooperative studies have also been successfully conducted.

The steady growth in the extent and character of the service in the state has thus so justified itself that it has had the support of the succeeding political administrations without exception since 1914; and recently under the present commissioner of health, Dr. Parran, the service has been still further extended into the broader field of pathology.

In 1930, Franklin D. Roosevelt, then governor, appointed a commission to advise him in regard to the administrative and legislative aspects of public health in New York State.⁵ Two subcommittees of this commission, one dealing with the control of cancer, the other with the development of laboratory service in particular, reported separately, stressing the importance of an extension of the system of approval—already developed so successfully in the diagnosis of communicable disease—to the examination of tissue and the diagnosis of neoplastic disease.

The laws of the state were amended at the next session of the legislature, to authorize the Public Health Council to establish regulations in the Sanitary Code, prescribing the qualifications of surgical pathologists in laboratories receiving approval by the State Commissioner of Health.

The Code was also amended to provide for the submission to such laboratories of "representative specimens, or sections for microscopic examination, of tissue removed at operation or at necropsy which require laboratory examination as an aid in the diagnosis, prevention, or treatment of disease or to determine the cause of death." These new responsibilities relating to the approval of laboratories for surgical pathology are administered by the Division of Laboratories and Research

in consultation with the State Institute for the Study of Malignant Disease. Histological examinations of tissue specimens have been made in the Division of Laboratories since 1914. The work has always had the helpful support of the State Institute and of Professor James Ewing, consulting pathologist to the laboratory, who, from the beginning, has been deeply interested in developing higher standards of laboratory service in surgical pathology and in the diagnosis of neoplastic disease.

Briefly, the Sanitary Code requires surgical pathologists to be graduates of schools of medicine recognized by the Regents of the University of the State of New York, and licensed to practise medicine, or eligible for examination for license to practise medicine, in the State of New York; it is further required that they have an adequate knowledge of pathology, and, subsequent to graduation, at least 4 years' training and experience in pathological work approved by the Public Health Council, of which at least 1 year shall have been devoted to training and experience in the diagnosis of neoplastic disease: provided, that under special conditions any or all of the qualifications relating to education or experience may be waived by the Public Health Council.*

Approval of laboratories in New York State is entirely voluntary. Nothing in the Public Health Law or Sanitary Code requires a laboratory to become approved. The physician, however, is obligated to submit certain types of specimens to approved laboratories. Thus, very appropriately, the responsibility for having necessary work done in a laboratory that has met adequate standards is placed with the physician who is in charge of the patient.

* The privilege of the waiver has rarely been exercised and only in the case of applicants whose qualifications, while not exactly conforming to the requirements specified, have been fully equivalent to them.

For years, it has been our practice, before issuing approval to a laboratory, to have the director or bacteriologist in charge, provided he is qualified by education and experience, demonstrate his ability by the examination of series of specimens furnished for this purpose. Similarly, candidates now examine a series of sections of tissue representative of the type of material which might be expected from a general surgical service, before approval for surgical pathology is granted. The sections, 50 in number, are accompanied by pertinent information concerning the clinical history, operative and other therapeutic measures. These specimens have previously been studied independently by the pathologists in the Division of Laboratories and Research and those in the State Institute for the Study of Malignant Disease. Only those sections are included concerning which there has been accord in regard to the diagnoses and the suitability of the material for the purpose. Approximately 1,000 such sections are now available.†

The procedure has been to request the candidate to submit data concerning his training and experience and to sign agreements relative to the conduct of the work in the laboratory. Provided his qualifications meet the requirements of the Sanitary Code, he examines a series of the tissue specimens at the State Institute in Buffalo, the central laboratory in Albany, or the branch laboratory in New York City. Also, in a few instances the examination has been conducted at the candidate's own laboratory. Reference books are available if desired. The findings reported are considered by members of the staff

† Arrangements are being made for a museum from which sections of various types of lesions can be lent to directors of approved laboratories for review or special study. A number of pathologists in New York State, as well as in other parts of the country, have already contributed material for this purpose. As soon as the project can be organized fully, we are hoping that the service will be helpful, particularly to the directors of laboratories who do not see a large variety of surgical tissue.

of the Division of Laboratories and Research and the State Institute for the Study of Malignant Disease. If the results of the examination are satisfactory, a certificate effective to the end of the calendar year is issued to the laboratory, a procedure similar to that followed in approval for other phases of laboratory work. The certificate, which is subject to revocation, may be reissued each year, unless the surgical pathologist should sever his connection with the laboratory, or evidence should be obtained that the character of the work is not entirely satisfactory. The surgical pathologist also agrees to return the certificate, should he for any reason no longer be in charge of the work in the laboratory.⁶

On July 1, 1934, 59 laboratories in charge of 41 pathologists had received approval for surgical pathology. Six of these are in New York City, where the State Sanitary Code does not apply. The persons in charge of the laboratories there which have received approval by the State Commissioner of Health, usually have wished to act as consultants to directors of laboratories in other parts of the state. Five surgical pathologists have qualified who have not as yet accepted positions in New York State. As would be expected, almost without exception candidates who have had 4 years of intensive training under com-

petent pathologists and have been actively engaged in this field of medicine have qualified in the practical examination. On the other hand, it has been a most effective means of demonstrating lack of ability in this type of work. Thus far, 19 applicants have failed to qualify. Almost all of them either had not been examining surgical tissue as a routine procedure for a number of years, or their training and experience, while approximating that required, was not entirely satisfactory.

The spirit of coöperation shown by the pathologists in this effort to raise the standards in surgical pathology has been most gratifying. Few question the importance of the service which a well qualified resident surgical pathologist can render. Already the effect of the program on the decentralization of laboratory work for the state has become evident.

The Industrial Hygiene Section 1914-1934*

EMERY R. HAYHURST, M.D., PH.D., F.A.P.H.A.
State Department of Health, Columbus, Ohio

SOME 25 years ago, a few persons, principally physicians but some economists, had appeared in the country who were aroused at the menace of occupational diseases. These began to associate themselves more or less in the subject of industrial hygiene. Now and then for half-a-century past someone had written upon the subject. In 1902, C. F. L. Doehring, a student of George M. Kober's at Washington, made the first official survey of industrial hygiene in America. This was done under the Hon. Carroll D. Wright, Commission of the Department of Labor, and the survey was made in the government shops in Washington. In 1905, Massachusetts was investigating its factories under Dr. William C. Hanson. In February, 1908, Dr. George M. Kober, while Secretary of President Roosevelt's Homes Commission, published a volume upon the subject, *Industrial and Personal Hygiene*. In the same year valuable articles by Dr. George M. Price, Dr. C. T. Graham-Rogers, Dr. Frederick L. Hoffman, and Dr. W. Gilman Thompson began to appear.

In 1910, the Illinois Commission on Occupational Diseases finished its survey under the direction of Dr. Alice Hamilton and the guidance of Prof.

Charles R. Henderson, Dr. Ludvig Hektoen, and others, and in June of the same year the First National Conference on Industrial Diseases met in Chicago at the call of the American Association for Labor Legislation under the guidance of Dr. John B. Andrews, Prof. E. R. Commons, Prof. Henry W. Farnam, and Dr. Henry B. Favill. Also, in New York City in 1910, Dr. Thompson started the first clinic on occupational diseases. This was followed in 1911 by the establishment of another at Rush Medical College, Chicago, by the writer, who had been with the Illinois Commission above mentioned.

Following these activities came those of the U. S. Bureau of Labor Statistics, the U. S. Bureau of Mines, the New York State Factory Investigation Commission (under Price in 1912-1914) and others; also, the impetus given by the XV International Congress on Hygiene and Demography held at Washington in 1912.

Hence, it was not at all surprising that a number of the persons concerned in these activities met at the Jacksonville, Fla., meeting of the American Public Health Association, held in December, 1914, and petitioned for a Section on Industrial Hygiene. This petition was granted and the new Section was the 5th in the list of 10 sections now composing the Association.

A special symposium of 4 papers on industrial hygiene was given at the

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

Jacksonville meeting, *viz.*, by George M. Kober, E. R. Hayhurst, John B. Andrews, and C. T. Graham-Rogers (in the order presented); and it is a striking fact that all of the following persons read papers in the various sections at that meeting which bore directly upon the subject; C.-E. A. Winslow, J. W. Schereschewsky, John A. Landis, William F. Snow, B. S. Warren, George E. Tucker, Irving Fisher, Philip Jacobs, D. D. Kimball, Earl B. Phelps, G. L. Ruehle, J. W. Trask, George S. Whipple, Slade, Carl Alsberg and Feldman. The following, likewise, took part in the discussions which followed: William A. Evans, Frederick L. Hoffman, Charles J. Hastings, Woods Hutchinson, Eugene L. Fisk, William C. Hanson, Thomas R. Crowder, Frederick S. Lee, Gustave F. Reudiger, Curtis C. Lakeman, Cressy L. Wilbur, Robert Olesen, Louis I. Dublin, James A. Miller, W. S. Rankin, E. L. Thorn-dyke, Roger G. Perkins, Deacon, and Selskar M. Gunn—the last named then Secretary of the Association.

The next Annual Meeting was held at Rochester (1915) where Dr. Kober was appointed temporary chairman who named a nominating committee consisting of George M. Price, J. W. Schereschewsky, C. D. Selby, Gillihan, and Louis I. Harris. The new Section held 4 sessions, and the following presented papers in the order given: J. W. Schereschewsky, George M. Price, C. D. Selby, W. I. Clark, Routsong (of Dayton), E. R. Hayhurst, William F. Snow, Louis I. Dublin, E. L. Fisk, Harry A. Mock, DeLeon, Coleman, Haven Emerson (for Louis I. Harris), W. Gilman Thompson, Kristine Mann (not present but paper read by title and summary), W. H. Rand (not present but paper read by title and summary), G. C. Farnum, A. J. Lanza, C. E. Armstrong, I. M. Rubinow, John B. Andrews, W. D. Yapple (not present), C. T. Graham-Rogers, and Victor C.

Noonan. In addition to those named, discussions of papers were made by George M. Kober, Alice Hamilton, Louis Schwartz, Meyers, Holden, Konrad, Gillihan, C. E. Ford, Theodore B. Sachs, P. S. Platt, S. M. McCurdy, J. M. Woltz, Lee K. Frankel, Victor C. Heiser, V. A. Moore(?), Eugene L. Fisk, W. S. Watkins, John W. Kerr, E. L. Pettibone, George T. Palmer, Brewer, I. A. Lanahan and David L. Rouch.

The first officers of the Section were elected at the third of the four sessions held in Rochester, and were: George M. Kober, *Chairman*; Alice Hamilton, *Vice-chairman*; E. R. Hayhurst, *Secretary*. By common assent and for a number of years the officers succeeded from Secretary to Vice-chairman, to Chairman, and then to Section Member of the Advisory Council which the Association then had.

The names of many not already mentioned were added to membership in 1915, and in 1925 were still on the roster of this Section, *viz.*: Arthur B. Emmons, II, C. C. Elliott, Lloyd Noland, Francis D. Patterson, Alfred E. Shipley, E. C. Jackson, R. W. Corwin, Charles F. Horan, Victor C. Safford, Millard Knowlton, Charles W. Cranshaw, Charles S. Prest, J. T. Black, Easton, Mull, A. J. Orenstein, Anna M. Richardson, D. B. Lowe, J. E. Rush, and C. C. Young.

In 1916, the Section held five sessions at the Cincinnati meeting and added more names well known to us, such as Otto P. Geier, George L. Apfelbach, H. R. M. Landis, Richard A. Feiss, F. E. Deeds, Royal Meeker, and others, and we had many at our sessions who visited from other Sections.

The successive officers of the Section and the annual places of meeting are shown in the table on the next page.

The World War greatly stimulated interest in industrial hygiene, added materially to the membership of the

Year	City	Chairman	Vice-Chairman	Secretary	Councillor

Those named in parentheses filled the offices specified, at certain meetings, due to the absence of the elected officers. Section representatives on the Advisory Council were discontinued in 1923. The 3 Section officers are now members of the Governing Council of the Association. In addition, the Section has an advisory committee called the "Section Council" composed of the 3 officers and 5 fellows, 1 of the latter elected each year to serve 5 years. The Section also has 1 representative on the Editorial Staff of the Association and 1 on the Committee on Eligibility.

Section, drew in many medical and welfare directors of industrial establishments, and at the same time saw the formation or extension of other organizations in the field principally associated with the general safety and industrial economic movements. Sheer want of space does not permit the mention of more names well known to us, but the membership was upward of 75-90 persons during this period.

Following the war and perhaps due somewhat to the distant meetings held successively in New Orleans (1919) and San Francisco (1920), a slump occurred both in attendance and interest at the Annual Meetings although probably not afflicting the membership of this Section more than that of others. As a matter of fact, however, the "old guard" withdrew considerably from active participation, due partly to some developing special lines, but fundamentally, I think, for two other reasons explained below. It was not

because at the Annual Meetings the activities of other Sections conflicted directly, as some of us said, with those of the Section on Industrial Hygiene, or to the extending growth of other organizations interested in specializing particular phases of the subject, so that many of us came to belong to several organizations. It was due, first, to the fact that government and convention everywhere were, and still are, devoting time and energies to extending *accommodations* in the shape of rehabilitation and occasionally compensation (not that these things are not laudable), instead of devoting resources to *prevention* and, secondly, because it was difficult to discern the function of the Section any more when it was realized that other public health workers were not looking upon the health of the worker or of the work place as a part of their genuine programs! And why? Plainly because it was and is not yet the "style," and because the laws in practically every

state have placed such health activities largely in other than health departments. In two or three states this has worked out pretty well, but the careful observer knows and sees the results in all the rest. This is the Gordian knot then to be cut in America: Industrial hygiene under other than medical and health supervision.

Public health workers—sanitarians of all descriptions and professions—must get into this “mess”—I know no better word to define it. This is a health matter, not something to be shelved on laymen. Ten years ago, Dr. C. O. Sappington (*Journal of Industrial Hygiene*, VI, 3:94 (July), 1924), of this Section, found that sickness caused 20 times as many cases of absenteeism as accidents, and was responsible for 7 times as much time lost from work, from which it would seem rational that any program for solving the problem of industrial disability intelligently must recognize the health causes while not relaxing vigilance in regard to accident causes. This in itself makes the whole subject worth every physician's and sanitarian's attention. Is organized government, as represented by health or labor departments, doing its duty in this matter? We think not. We will put it stronger—we know it is not, because we have investigated the subject, perhaps ever so superficially, and found that the most unguarded machinery in the entire health field is the health of the worker while on the job.

As evidence of this we have seen the disease, tuberculosis, the great criterion disease of environmental health conditions, recede from 1st to 7th place in the list of causes of death in the general population in the past 20 years, but the recent monograph, “Death Rates and Occupations,” by Jessamine S. Whitney of the National Tuberculosis Association, shows that tuberculosis was the second cause of death among *principally occupied males* in

1930, with a rate of 95.1 per 100,000, or next to heart disease. A recent study of Ohio vital statistics showed that, in *mechanical and manufacturing industries*, the tuberculosis death rate for *females* was 118.1 as compared to 96.6 for males, for the year 1929, and that, in 1930, among those so employed, the ratio of female deaths to males was nearly 6 to 1 (*Ohio Health News*, VIII, 19:3 (Oct. 1), 1932).

At the present time the greatest morbidity and mortality is not associated with childhood any more, but with chronic degenerative diseases which appear in adult life, and are particularly rampant in the industrial working classes. Certainly no health program is complete without attention to this serious situation, and I believe no health department is doing its full duty that does not recognize occupational diseases and provide for their reporting and prevention, the same as for communicable diseases, food poisoning, etc.

Our Secretary, B. S. Coleman, informs me we now have 139 members in the Section on Industrial Hygiene, of whom 42 are Fellows, and 97 are full-fledged active members. Furthermore, 16 new applications for Fellowships have been approved for election at this meeting. What better nucleus is needed to consider the facts, policies, scientific aspects, and promotion of a dutiful program in industrial hygiene in this country? To this end we now have 8 standing committees (in addition to the Section Council) which are reporting at this meeting.* Nearly all of these committees were appointed at the Cincinnati meeting in 1927, and nearly all of their respective annual reports

(published, first, in the *American Journal of Public Health*, but since 1930, in the Association's *Year Book*) have gained world-wide recognition as authoritative and unbiased, and representative of the efforts of the best brains the country affords in industrial hygiene. It has also been a great credit to have belonged to any of these committees where hard work was entailed, no funds were available, and most work had to be done by correspondence.

TO WHAT EXTENT HAVE THE MAJOR PROBLEMS OF INDUSTRIAL HYGIENE CHANGED IN THE LAST 20 YEARS?

The average age at death for the industrially employed has advanced by several years, but is still some 6 to 8 years lower than that for those in agricultural pursuits.

Occupational dermatoses are recognized as by far the most widespread of characteristic occupational diseases, and the group of oils, greases, and cutting compounds usually leads, with cleaning agents and petroleum distillates next up.

Lead poisoning maintains the statistical lead as the most costly and no doubt the most prolonged of the disabling occupational diseases, although the incidence of severe cases is lower than formerly. Its diagnosis by refined chemical methods, and the discovery of lead ingestion and secretion in the average individual have been a development of recent years and by members of this Section, notably, Aub and Kehoe. The discovery of lead lines in the long bones by use of the X-ray should be mentioned.

The hazards from spray painting, enameling, lacquering, etc., first recognized in 1915 by an early member of this Section, Dr. R. P. Albaugh, have enormously extended as innumerable poisons have come to be applied by this method.

"Dust phthisis" of 20 years ago, and

"pneumoconiosis," barely mentioned at that time, have gradually contracted down to nearly one great cause producing the disease "silicosis," while the theory of sharp cutting edges has faded out to a more rational mechanical-blockage-and-slow-chemical reaction of some sort. Chest X-rays, first developed as a group-study in 1915 by Lanza (another of our charter members); an extension of animal experiments and the development of dust counts by others of our members; and, unfortunately, costly litigation as a consequence of lack of control, have all come during this period.

Certain disastrous poisons such as benzol, anilin, carbon bisulphide, and carbon monoxide, which were rampant 20 years ago, have largely disappeared as industrial hazards, although some others connected with explosives, "anti-knock" agents, cleaners, solvents, and electro-plating, have taken their places, and we find the names of many of our members attached to these problems, notably Sayers and Yant and their staffs, McCord, Smyth, Phil Drinker, Alice Hamilton, Adelaide Ross Smith—space alone limits naming more.

"Corrosive and toxic agents" are still classified with "flammable agents" in most factory and labor statistics!

Pneumonia has come to be recognized as a potent cause of death among heat exposed workers (under cover), while the administration of common salt in the prevention of heat stroke has been a real discovery.

Radium emanations, lung cancer, and, at least in England, mule spinner's cancer, have appeared as rare but fearful occupational diseases. Indeed, industrial exposures have shown how to produce cancer at will, and may lead to the elimination of this scourge.

Ventilation has developed to the phase of "effective temperature" and "radiation balance," but with very little industrial application, or even com-

mercial recognition, while "air-conditioning," especially for warm weather, is just knocking at industry's door.

Rarefaction has been shown to be essentially an oxygen-want question.

Illumination, especially sufficient illumination, appears to have been satisfactorily solved for most all industrial workers.

Natural methods of resuscitation have all but supplanted the unphysiological mechanical devices of earlier days, while the addition of a stimulating amount of carbon dioxide to oxygen has been an invention of the past decade.

Rehabilitation, including occupational diseases as well as injuries, has come to be a government function in several states, and some of our members, particularly Kessler, have had a leading part in this important matter.

I must also mention that the Section

on Industrial Hygiene has always enjoyed the fullest coöperation of the Editor-in-Chief, Dr. M. P. Ravenel. The vast majority of our papers have been published in the *American Journal of Public Health*, and we have been especially favored with space for abstracts, book reviews, bulletins and reprints.

Finally, the terms "occupational disease" and "industrial hazard" have not yet been standardized or even defined to everyone's satisfaction. A "specific test for fatigue" has not yet been discovered, nor, I might say, a method of correlating a speaker's everlasting dynamics with the increasing weariness of the audience.

In closing, I risk one prophesy only: This Section is going to grow tremendously in influence and membership in the next 20 years.

Use of Dinitrophenol in Nutritional Disorders^{*}

A Critical Survey of Clinical Results[†]

MAURICE L. TAINTER, M.D., WINDSOR C. CUTTING, M.D., AND
A. B. STOCKTON, M.D.

*Associate Professor of Pharmacology; Resident in Medicine; and Instructor
in Therapeutics; Stanford University School of Medicine,
San Francisco, Calif.*

A LITTLE over a year ago, our first clinical report on dinitrophenol appeared in the *Journal of the American Medical Association*.¹ The interest in and enthusiasm for this product were so great that its widespread use has become a matter of some concern in public health. The total amount of the drug being used is astonishing. For instance, during the past year, the Stanford Clinics have supplied to physicians, or to patients on physicians' prescriptions, over 1,200,000 capsules of dinitrophenol of 0.1 gm. each. Since the usual daily dose is about 3 such capsules and the average duration of treatment about 3 months, this corresponds to 4,500 patients treated with the drug in a year. In addition, upward of 20 wholesale drug firms are marketing the compound, which suggests that a considerable population is being medicated. Probably at least 100,000 persons have been

treated with the drug in this country alone. But this is not all, for reports of its clinical use have also appeared in the medical press of Canada, Great Britain, France, Sweden, Italy, and Australia. Therefore, it appeared timely to summarize the accumulated knowledge of the clinical effects of this drug, and to assess the results critically, in order to determine, if possible, the present status of this new therapeutic agent.

HISTORY

We began to study the actions of alpha dinitrophenol 2-4 first in animals and then in patients, in 1931, being stimulated to do so by the animal experiments of Heymans,² who used a similar compound, namely, dinitronaphthol. Dinitrophenol was not new, since it had been known as a dye for about a hundred years, and as an industrial poison for 32 years.³ There was some interest in its toxicology during the war, due to poisoning in munitions factories. Fundamental investigations of the actions of the compound were made at that time by Magne, Mayer, and collaborators in France, although their studies were not published until 16 years

^{*} Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

[†] Supported in part by grants from the Rockefeller Fluid Research Fund of the School of Medicine, Stanford University, and by Grant 320 from the Committee on Scientific Research of the American Medical Association.

later, *i.e.*, in 1932.⁴ Our experimental results⁵ and those of all other investigators are in essential agreement on the remarkable powers of dinitrophenol for augmenting oxidative metabolism by a direct action on the tissues or cells. Prior to our work, there was no indication in any of the published papers that this potent metabolic stimulant might be of any therapeutic usefulness. Therefore, when we first drew attention to the possibility of producing metabolic changes in man with small non-toxic doses of dinitrophenol, there was presented to the medical profession a new tool for use in metabolic disorders.

MEDICAL USES

It has been shown^{1, 6, 7, 24} that dinitrophenol can be used to keep the metabolism at an increased level for prolonged periods of time. An increase in the metabolic rate of about 50 per cent can be maintained in most patients without difficulty, by proper selection of dosage; in fact, greater increases have been repeatedly produced.

Rabinowitch and Fowler¹⁸ state that they have found difficulty in standardizing the oral dose because of individual variability. Examination of their data shows that, when the probable error of clinical metabolic readings is considered, the agreement is as good as could be expected. Variability in sensitivity to drugs of all kinds is a matter of common knowledge, so that, if perfectly reproducible changes were claimed, it would throw doubt on the validity of the observations. In contrast to Rabinowitch, Dunlop⁷ finds a reasonably good agreement between the metabolic stimulation and the size of the dose, which confirms our experience. However, in treating ambulatory patients⁶ it is desirable to proceed conservatively by starting with small doses and increasing them, if necessary, according to the degree of response elicited.

When the drug is taken in adequate

dosage, the increased metabolic activity burns extra fat and carbohydrate and thereby reduces body weight.⁶ It is very interesting that the protein does not seem to be appreciably affected in the combustion process, as indicated by nitrogen excretion. Accordingly, the tissue framework tends to be conserved.^{7, 8, 14} In a preliminary report on the loss of body weight in obese individuals,⁶ it was stated that losses of 2 to 3 pounds a week could be obtained with doses of dinitrophenol which were well tolerated. Three other groups of workers have confirmed this result in smaller groups of patients,^{7, 9, 10} and it is now a common experience with many practising physicians.

Dunlop⁷ compared the relative efficiency of thyroid and dinitrophenol in reducing weight in a few selected patients. He found that thyroid upset the water balance of the body in such a way as to cause at once a rapid loss of weight by dehydration. On the other hand, dinitrophenol reduced the weight less rapidly, but in proportion to the metabolic increase and not by an effect on water balance. His experimental results do not satisfactorily establish his conclusion that "even in maximum therapeutic doses it (dinitrophenol) does not compare, as a weight reducer, with thyroid"; since he used both drugs for only a few days at a time, and during these periods the weight changes were so small as to be readily accounted for by shifts in the water balance.

The amount of permanent weight change that can be produced by dehydration in non-edematous patients is not great enough to be important where any significant amount of weight is to be lost. If this were not the case, simple dehydration procedures would answer the needs of this difficult clinical problem. Therefore, it appears to us that, before the therapeutic efficiencies of these drugs may be satisfactorily

compared, it is necessary to make observations over long periods of time, during which more than a few pounds are lost. It has been indicated by us in several publications^{11, 12} that dinitrophenol cannot be used to replace thyroid secretion. It is therefore misleading to compare the intensities of their actions since they act so differently qualitatively.

Since dinitrophenol can increase the tissue metabolism by a direct action on the cells, without producing the side-actions which accompany metabolic stimulation by thyroid, it offers, theoretically at least, interesting possible applications in medicine, besides its use in obesity. For instance, there have been reported interesting effects in psychiatric conditions,^{13, 14} and failure to relieve myxedema,^{7, 18} and many other studies are in progress. Because of its widespread and probably sometimes indiscriminate use by large numbers of people, it is pertinent to consider possible harmful effects from the compound.

FATAL EFFECTS

In experimental animals, a large enough dose of dinitrophenol will stimulate the heat production to the point where fatal fever results. The heat production may be increased 1,200 per cent, the body temperature increasing 0.2° C. per minute. Under these conditions, death is caused by heat rigor, that is, by heat-coagulation of tissues. Exactly similar effects can be produced in man provided a large enough dose is taken. This was seen occasionally in munition workers during the World War, who absorbed large amounts of dinitrophenol through the lungs or skin.

The first case of fatal poisoning from the therapeutic use of the drug was that of a physician who took a tremendous dose on two separate occasions, with the alleged object of treating an

imaginary syphilitic infection.¹⁵ In his second administration, he took 5 gm. of the drug as a single dose, which is a 17 day supply for most patients. A fatal fever resulted, with death in 12 hours.

The second death was a girl who bought the drug on her own responsibility from a druggist. On the fourth day of medication, she took 0.8 gm., which caused a fatal pyrexia.¹⁶ Since the daily dose during the first week or two should be only 0.1 gm.,⁶ it is obvious that this girl took a very excessive dose. In fact, it was a larger dose than we have ever used therapeutically, even after months of continuous medication.

The third death occurred in a psychiatric patient who was receiving doses within the therapeutic range.¹⁸ The clinical history of this patient's illness and death is completely at variance with the known actions of dinitrophenol, since there was a protracted course of illness and an absence of serious fever. Also, the autopsy and clinical studies were so incomplete as to preclude a correct diagnosis of the cause of death.

These three cases represent the reported fatalities from dinitrophenol. If the third case be excluded because of the question as to the true cause of the death, it is seen that neither of the other two cases was due to the use of the drug in the usual therapeutic doses. When one considers that some one hundred thousand patients have been treated with this exceedingly potent therapeutic agent, it is a matter of some gratification to know that fatalities have not been more numerous. It might be added in this connection that fatalities from the fever of dinitrophenol can be largely prevented, in animals at least, by chilling the skin with ice packs and by giving oxygen inhalations.¹⁷

There are also a number of observed, or theoretically possible, deleterious actions, which do not result fatally. These may be discussed according to the

organs involved, *i.e.*, skin, liver, kidneys, circulation, and gastrointestinal tract.

SKIN REACTIONS

In a series of 113 obese individuals,⁶ we observed the presence of skin rashes in about 7 per cent of cases. The rashes consisted of maculo-papular dermatitis, urticaria, or angio-neurotic-like swellings of the skin, accompanied by pruritus and occasionally by desquamation. There was usually a prodrome of itching before the skin lesions developed. Four similar cases have been reported to date,^{9, 19, 20, 21} and many more than these have undoubtedly occurred. Dintenfass²² has recorded still another case in which the dermatitis was associated with congestion of the middle ear.

The inference might possibly be drawn from certain reports that a Derrien reaction with the urine could be used as a means of predicting possible lack of tolerance to the drug. This idea rests on a misunderstanding of the nature of the test; it is merely the well known diazo reaction, which is positive in the presence of amino-nitrophenols. Hence, it only indicates that dinitrophenol has been absorbed in the body and has appeared in the urine in a reduced form. During the war, this reaction was used solely as a means of identifying those workers whose exposure resulted in appreciable absorption of the drug.²³ Bolliger has recently cast doubt on the value of the reaction for even this purpose.²⁴

Another possible way of predicting dermal intolerance is by the usual allergic skin tests. Frumess²⁵ states that, in a case of urticaria, he was able to reproduce the skin-sensitivity by passive transfer. However, an extensive series of skin tests²⁵ in patients with and without skin rashes, who received dinitrophenol therapeutically, has failed to bring out any evidence that skin-

sensitivity can be detected by patch, scratch, or intradermal wheal tests. Passive transfer tests were also negative. These methods would therefore seem unpromising as means of selecting patients for dinitrophenol medication.

Since the skin rashes may be very unpleasant or alarming in some cases, they constitute the main disadvantage in the therapeutic use of dinitrophenol. A saving feature, however, is that about half the patients who have had one skin reaction are able, after a short interval, to resume the medication without further difficulty.

LIVER DAMAGE

Much has been made by some editorial writers and clinical reporters of the possibility that dinitrophenol might damage the liver. This has been based mainly on reasoning by analogy from picric acid and other compounds. Since the dinitrophenol has a yellow color, which imparts an icteric tint to the blood plasma, it may be mistaken for the bile pigments of jaundice.²⁶ The differentiation from the latter may be readily made by adding dilute hydrochloric acid to the plasma which decolorizes the dye. In one patient suspected of liver injury, Rabinowitch¹⁸ found only a slight increase in the bilirubin in the blood and no change in the urobilinogen. At the next examination of this patient, the findings were all negative. Another case where liver injury was apparently produced has been recently reported by Sidel.²⁴

We have seen no evidences of damage to the liver in our clinical cases,⁶ and at this time we may add more extensive data on this question. In 17 patients who were given an average of 0.3 gm. of sodium dinitrophenol daily for from 1 to 5 months, there were made 22 determinations of the icteric indices of their acidified blood plasmas. The average value was 8.2 units with a range of from 4.8 to 16.3. Fourteen

determinations on non-medicated patients gave an average index of 7.6, with a range of from 4.2 to 10.0. In 45 patients, the bilirubin content of the blood serum was determined by the van den Bergh reaction.⁴ This group of patients received an average daily dose of 0.3 gm. (range 0.1 to 0.6 gm.) for an average period of 19 weeks (range 2 to 50 weeks). The average total amount of the drug taken was 36 gm., with a range of from 2.8 to 122.5 gm. In these patients, the bilirubin averaged 0.29 units, with a range of from 0.13 to 0.79 units. Only 2 patients of the 45 showed values over 0.5, but these had no demonstrable clinical evidence of liver disturbance.

If the dinitrophenol injured the liver progressively, it might be expected that the bilirubin of the blood would increase with the total amount of the drug taken. The following tabulation shows that no such increase was present, which further supports the conclusion that damage to the liver was not produced in these patients.

<i>Average total amount of dinitro- phenol taken in gm.</i>	<i>Number of cases</i>	<i>Bilirubin units (average)</i>
0 - 10.0	12	0.27
10.1- 30.0	8	0.34
30.1- 40.0	14	0.32
40.1- 80.0	8	0.22
80.1-122.5	4	0.31

The van den Bergh reaction was repeated in 6 patients some time after stoppage of the dinitrophenol medication. These patients had been off the drug for an average of 36 weeks when they showed an average bilirubin content of 0.24 units (range 0.15 to 0.40). Accordingly, there was no evidence of delayed liver damage.

It has been observed by us¹⁵ and by Poole and Haining¹⁶ that, in fatal dinitrophenol poisoning, destructive

changes may occur in the liver as well as in other viscera. It must be remembered that death in these cases was accompanied by a very high fever, which in itself is enough to account for the morphological changes observed in the liver cells. The usual therapeutic doses of the drug produce no change in body temperature and also no evidences of change in liver function. However, the possibility must still be left open that in occasional patients an idiosyncrasy may exist which might mediate damages to the liver.

KIDNEY

If dinitrophenol in therapeutic doses damaged the kidneys, this would be manifested by albuminuria and related changes. Such evidences could scarcely go undiscovered, since urinalysis is such a common routine procedure. Hence, it becomes of significance that only 1 possible case of renal injury has been reported thus far. Rabinowitch and Fowler¹⁴ reported 1 patient who developed an albuminuria and high blood urea during dinitrophenol medication. Three weeks later, the urine, and the blood urea and creatinine were all normal. In our patients⁶ albuminuria has never been produced by the drug, but on the contrary a limited number of patients have lost their preëxisting albuminurias during the medication. Our experimental studies^{27, 30} on animals have also shown the drug to be quite devoid of toxic effects on the kidneys. Therefore, the possibility of renal damage would appear so remote as to cause little or no concern in the therapeutic use of the drug.

CIRCULATION

One of the most striking features of the metabolic stimulation of dinitrophenol is a lack of significant changes in blood pressure or pulse rate, unless therapeutic doses are exceeded.^{1, 6} That is, the metabolism may be increased by

* The van den Bergh data were obtained with the assistance of Elizabeth Hines.

as much as 50 per cent without demonstrable changes in circulatory activity. This phenomenon is in striking contrast to the effects of thyroid administration, where circulatory changes are a marked feature of the symptom-complex. Confirmation of this early finding has been given by Looney and Hoskins,¹⁴ Rabinowitch,¹⁸ and Dunlop,⁷ and more recently again by ourselves working under different conditions.²⁸ We have observed that, when a patient feels very hot and flushed, there is a rise in venous pressure. This may be the result of vasodilatation in the skin rather than the metabolic stimulation, since the venous pressure changes do not correlate with those of metabolism. Rosenblum²⁵ observed in patients whose metabolic rates were increased 37 per cent by dinitrophenol, that the circulation time from the arm to the tongue was unchanged. This would be in keeping with the lack of changes in the blood pressure and pulse rate previously reported.

Masserman and Goldsmith¹³ have made the rather startling claim that 5 out of their 18 psychiatric patients showed toxic effects characterized by a fall of blood pressure, tachycardia, stupor, etc. No such effects were observed by Looney and Hoskins¹⁴ in a similar group of patients, nor in upward of 300 non-psychotic patients observed by us. Not a single case of hypotension has been observed by, or reported to, us and none has been reported in the literature. The unconfirmed and possibly misinterpreted observations of circulatory changes by Masserman and Goldsmith, taken together with an unexplained death among their patients, suggests that there may have been some error in the therapeutic procedures they used, such as the possible use of a wrong isomer or an impure preparation of dinitrophenol.

Patients who have hypertension can be medicated with dinitrophenol like

other patients. As they lose weight, the hypertension is usually improved⁶ and the associated symptoms are ameliorated.

BLOOD

In studying the possibility that dinitrophenol might affect the blood, both the red and white corpuscles must be considered. Thus far we have not made extensive red cell counts in patients receiving dinitrophenol, but there have been no evidences of anemia, even after months of medication. The oxygen capacity of the blood of 15 patients was determined for possible evidences of injury to the respiratory function of the blood. Since the normal oxygen capacity of the blood varies from 18 to 21 vols. per cent and in these medicated patients the average value was 19.5 vols. per cent with a range of from 18 to 22 per cent, there is no reason to believe that the blood was injured. These patients received an average of 0.3 gm. sodium dinitrophenol daily, for an average period of 6 weeks. The addition of sodium dinitrophenol, in concentrated solution to several specimens of blood did not change the oxygen capacity. Therefore, the drug does not appear to affect the hemoglobin of the blood *in vitro* and *in vivo*.

Study was also made of the fragility of the red cells of these same patients to determine whether there was any increased tendency of the cells to hemolyze. The cells were exposed to various strengths of hypotonic salt solution and the concentrations at which hemolysis began and was complete were noted.²⁹ Hemolysis of normal cells begins at from 0.46 to 0.38 per cent concentration and is complete at from 0.34 to 0.25 per cent. With the cells of the medicated patients, the hemolysis began at an average of 0.44 per cent, with a range of from 0.42 to 0.46 per cent, and was complete at an average of

0.31 per cent, with a range from 0.25 to 0.38 per cent. Since these values were all within the normal range, there was no evidence of alteration in fragility of the red cells.

Current emphasis on the problem of agranulocytosis makes it desirable to observe the white blood cells in patients receiving dinitrophenol. We have seen no cases of malignant neutropenia, or of any condition which might be ascribed to a reduction in the number of white blood cells, among the considerable number of patients treated at Stanford. In addition, we have examined the blood and bone marrow of dogs given extra-therapeutic doses of dinitrophenol daily for 6 months without finding any abnormalities.³⁰ However, Hoffman, Butt, and Hickey³¹ have reported 1 patient who developed a neutropenia while taking dinitrophenol, and who recovered. A second case has recently been reported,³⁶ and other unpublished cases have apparently occurred.³³ Agranulocytosis has been reported in association with medication with a large number of unrelated drugs, and even in the absence of medication. Although the cause of agranulocytosis is not yet understood, it is probable that the underlying factor common to all cases is a defective bone-marrow which requires some, and apparently sometimes a relatively insignificant, exciting cause to precipitate the crisis. Given such bone-marrow, it is conceivable that many extraneous agents, physical, bacterial or chemical, and including even dinitrophenol, might initiate the clinical syndrome. The fact is that the vast majority of patients can take massive doses of the various drugs alleged to cause agranulocytosis without damage to white cells, and yet in a sensitive individual even a small therapeutic dose of one of these drugs may suffice to precipitate the condition. However this may be, we shall continue to examine all patients receiving dinitrophenol with

the possibility of agranulocytosis in mind, and hope to present more specific data on the question at some future time.

GASTROINTESTINAL TRACT

Heymans has stated that dinitrophenol causes very severe gastroenteritis and loss of appetite, and suggested that the loss of weight was due to the failure or inability of the patient to eat.³² In our very large series of patients, there have been only 3 cases with digestive complaints during the medication with dinitrophenol. These complaints lasted only for a few days, such as might be expected from a slight dietary indiscretion. The claim that this drug is a severe irritant to the gastrointestinal tract of patients is unwarranted for doses of therapeutic range, according to our experience and to that of large numbers of physicians prescribing it. Tissues from the gastrointestinal tracts of dogs given the drug for 6 months by mouth also showed no evidences of abnormal changes.³⁰ Therefore, there is no good reason for postulating a hypothetical gastroenteritis as the cause of the loss of body weight in the face of repeatedly demonstrated metabolic stimulation which does adequately account for it.

DISCUSSION AND SUMMARY

It can now be said that dinitrophenol is of definite value as a drug for treating obesity and perhaps some other metabolic disorders. In the hands of the medical profession, it can be used with the maximum benefit and with minimum deleterious results. Unfortunately, its sale cannot be confined to physicians under present legal regulations. As a result, it can be, and is being, sold in patent and proprietary medicines under names which do not reveal its presence. A person buying such an anti-fat remedy over the drug store counter, with no more directions

as to its use, or warning of possible harmful effects, than the manufacturer pleases to put on the label, may run a serious danger of doing himself harm. This problem is particularly pressing since "obesity cures" are extensively bought by fat people for self-medication without diagnosis. Therefore, it would seem desirable that dinitrophenol be added to the poison list, and its sale regulated so it could not be obtained except on a physician's prescription.

In the first enthusiasm for a new drug, which has spectacular actions, it is to be expected that it may be used somewhat too freely. This we have consistently tried to prevent in the case of dinitrophenol by stressing the potential dangers of the compound when used indiscriminately. Certainly, it should not be used as a routine measure in any clinical condition. Obesity can be controlled in most cases by the physician who will patiently supervise the dietary regime. In other cases, thyroid or thyroxine may be needed. It is only when all other measures have been thoroughly tried and found ineffective, and when there is impelling need for weight reduction, that dinitrophenol medication, with a knowledge of attending risks, should be undertaken. Under these circumstances, the physician must balance the prospective benefit against the potential harm, just as he does with any therapeutic procedure, and give the patient his best chance.

This summary of the clinical effects and side actions of dinitrophenol shows that in some respects this drug is not ideal as a therapeutic agent, since it may cause certain undesired side-actions in a portion of the patients treated. However, this does not mean that it cannot be used safely under proper conditions. Investigations are under way in our own and many other laboratories to develop new compounds which may be better than this original or parent substance. It would be only a matter of chance, if

dinitrophenol happened to be better than any substitute that could subsequently be prepared. Therefore, it may be expected that the next few years will see other compounds brought forward and advocated. Perhaps some one of them may supplant alpha dinitrophenol as the agent of choice. However, this will in no way affect the great significance of dinitrophenol as having been the first foreign agent, or drug, to be demonstrated as a very potent and well nigh universal metabolic stimulant, which was available for experimental purposes and useful for alleviation of human infirmity.

Concurrent Immunizations

ANSON B. INGELS, M.D.

Director, Gila County Health Unit, Globe, Ariz.

ON December 11, 1933, I did 100 Schick tests on grammar and pre-school children who had received immunizing injections of diphtheria toxoid without previous Schick tests, and on reading them 3 days later found 91 were Schick negative. We were surprised at this result, as the individuals had been given toxin-antitoxin in 1930 and the toxoid in 1931 and 1932. The immunizing agents had been carried, unrefrigerated, over a hot desert for 96 miles, and therefore could not have been of the highest efficiency. After reading the Schick tests with this percentage of immunity, we looked to our sterilization and to the dosage of the Schick material, and could find no fault in either.

The next day we went to a settlement 114 miles from the Unit, where the same condition of giving immunizing injections for diphtheria obtained, and on reading the Schick tests found practically the same percentage negative.

In checking the inoculations given these 2 groups of school and preschool children, we found that they had been given simultaneous immunizations of toxin-antitoxin or toxoid with typhoid vaccine, and in many instances a smallpox vaccination had been done at the time of the primary injection. Later in checking our records we selected a group of 180 grammar school children in Miami and 350 school and preschool children in Hayden, who had had concurrent immunizing injections of diphtheria toxoid with typhoid-paratyphoid vaccine and smallpox vaccination, but

without previous Schick tests, and the percentage of Schick negative children ran the same. We therefore Schick-tested 3,000 children, most of the group being of grammar school age, who had had the diphtheria inoculations from 1 to 3 years previously but without Schick testing, with the result that the entire group who had received concurrent immunizing inoculations showed 90.7 per cent immunity. In this series we had watched sterilization carefully. The heated toxoid was carried and kept in thermos jugs that were properly iced so that the Schick control material would be properly refrigerated at all times. Pains were taken to see that each child got exactly 0.1 c.c. of the fluid in an intradermal injection. Faults in technic where the skin was penetrated have not been counted in this series. Where such faults occurred, however, the children were given the Schick test at the time of the readings of the other children in this group, and were then read 3 days after the original reading.

We found from records of the diphtheria immunizations in Gila County, that from 1930 to the end of the first half of 1933, 90 per cent had received simultaneous immunizing injections of the toxoid and the typhoid-paratyphoid vaccine. This was due largely, I believe, to the distance a former director and nurse were compelled to travel in order to immunize the school children, as it is 114 miles from the office of the Gila County Health Unit to the most northern school in the county, and 50

miles to the most southern. For this reason time was an element in the giving of immunizations, although the same conditions obtained in the schools at Globe, where the office is located, and at Miami only 6 miles away.

While we have done considerable Schick testing in children who did not receive concurrent immunizations, the percentage of those Schick negative has not yet been tabulated, our efforts having been spent in checking those Schick tests where concurrent immunizations had been given, and in those individuals where the alum precipitated toxoid was used.

The ages of those included in the 3,000 tests vary from 1 year to 12 years. In other words, the group con-

sisted of children who received the immunizing injections between the age of 6 months and 9 years. The highest percentage of Schick positive children was in the 8-10 year old group. The greatest percentage of Schick negative children who had received concurrent immunizations, was in the 1-5 year period.

Tabulations have not been made for age groups of the elapsed time from the primary injections to the Schick tests.

As there is little, if any, mention in the literature as to the higher immunity percentage found where concurrent inoculations are made, it seemed fitting to make this report of the 3,000 Schick tests made from December 11, 1933, to June 30, 1934.

Relapsing Fever Problem of California*

GEORGE E. COLEMAN

*The George Williams Hooper Foundation for Medical Research,
University of California, San Francisco, Calif.*

STATISTICS concerning the incidence of relapsing fever in California (39 cases of which 16 were unproven by blood examination), its clinical features as well as a general discussion of the epidemiology, have recently been given by Briggs.¹ Aside from the work at the Hooper Foundation, University of California, as far as I know there has been no detailed study made of the California strains isolated from human cases and wild animals. My results, to a considerable extent, with discussions of the work and opinions of numerous authors throughout the world, have been embodied in 4 articles already published. In this paper I will review some of my outstanding conclusions regarding the California strains thus far studied.

In general I may say that the morphological characteristics of the spirochete do not give us any criteria for the differentiation of species. The clinical disease in mice caused by the 8 California strains which I² have studied was practically identical in each except that some strains proved to be more virulent than others. As to the disease in guinea pigs there seems to be considerable difference in the clinical picture and in the individual susceptibility of these animals. While spirochetes are usually present, in certain

animals the cardiac blood examined in thick film every day for 22 to 23 days after inoculation never revealed spirochetes, though it was infectious for mice. The serum of these particular guinea pigs with cryptic infections was not protective for mice. The controls receiving serum alone were not infected. The blood had been centrifugalized at high speed for 3 hours and the serum kept in the ice box for 2 weeks.

The entire life cycle of relapsing fever spirochetes has not yet been revealed. The question of dosage required to infect animals and the stage of the disease at which the inoculum is taken is still of considerable importance. In my hands "negative blood" when infectious generally produces a mild disease. Studying Texas strains Kemp, Moursund, and Wright³ found that a small dose of negative blood produced positive results earlier and a more pronounced infection than larger amounts. It would have been interesting to have destroyed the viability of the invisible forms and to have made an attempt to evaluate the protective properties of the serum. Most other workers, as far as I know, have attributed different antigenic properties to the spirochetes of the various phases of the disease. As regards the dosage, in all this work to evaluate the comparative infectivity of spirochetes from different stages of the disease, consideration should be given to the presence or absence of spontaneous agglutination in the inoculum and the number of spirochetes present.

*Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1914.

For this purpose only washed spirochetes should be used.

Novy and Knapp⁴ and Kemp, Moursund, and Wright³ believe that the viability of blood kept *in vitro* depends upon the phase of the disease from which it was taken, relapse spirochetes dying out rapidly. These workers respectively kept blood 40 and 6 days. Gray⁵ did not find onset blood kept at 0° C. or at room temperature infectious for 40 days. While I have not kept whole blood as taken from the animal I² have added a few drops of whole uncitrated mouse blood (first relapse) to about 6 c.c. of defibrinated sheep's blood and placed it in the ice box. The blood has remained infectious for over 5 months. It is now our practice in carrying on our strains, in order to save time and animals, to inoculate mice from sheep blood every 2 or 3 weeks and place the onset blood from the infected mouse in fresh sheep's blood.

The California strains are infectious when fed to mice and by the conjunctival route in guinea pigs. I have been unable to affect the normal increase of spirochetes in the blood of mice at onset of the disease by the injection of the serum of hyperimmunized mice. This is contrary to the experience of Novy and Knapp.⁴

IMMUNITY

Passive immunity frequently can be conferred by the injection of homologous serums even of "recovered" mice if given several hours before the spirochetes while heterologous hyperimmune serum may protect if the spirochetes are added to it or if the serum is injected separately by the intraperitoneal route at the same time. In testing for active immunity with either homologous or heterologous strains, contrary to the opinion of most workers, it appears to make no difference from what phase of the disease the spirochetes for the test are taken. As to onset and first relapse

spirochetes, Kemp, Moursund, and Wright³ have confirmed my⁶ findings that there is cross-immunity between them. It is interesting to note that these authors have produced active immunity in white rats by intraperitoneal injections of heat killed spirochetes.

In my earlier work with 3 California strains I⁶ found that all were probably identical, and studied in comparison with *Sp. novyi* and *Sp. duttoni* I showed that 3 mice hyperimmunized (10 injections) with a California strain were protected against 4 injections of *Sp. novyi* (onset and relapse spirochetes). Mice less solidly immunized with *Sp. novyi*, which when received was less virulent than this particular California strain, were not protected against it. I then discussed the history of *Sp. novyi*, the findings of St. John and Bates⁷ in comparing it with the Panama strains and the possibility of a close relationship between it and the California strains.

In later work I⁸ showed that the serum of a "recovered" guinea pig very mildly infected by the conjunctival route with a Texas (Fall Creek) strain gave absolute protection to 3 mice inoculated with a Central California (Lake Tahoe) strain and marked partial protection against more virulent strains from Southern and Northern California. This tends to confirm the opinion several times expressed that certain Texas and California strains are probably identical. In the same paper I have discussed in detail the technic and sources of error in cross-immunity tests. Their correct application depends upon the determination as accurately as possible of the degree and duration of the immunity to the homologous strain of the immunized animals at the time they are to be tested and the *relative virulence* for the same animal species of the 2 strains to be tested against each other. In testing "recovered" or hyperimmunized mice against a heterologous

strain, aside from the usual normal controls it is well to inoculate 2 mice of the same series of "recovered" or hyper-immunized animals again with the homologous strain as additional controls.

Experience has shown that sometimes at a given point immunity diminishes very rapidly. When occasionally rare spirochetes of the heterologous strain appear after inoculation, showing incomplete immunity, one can thus sometimes form an opinion as to the probability that there was not absolute immunity at the time of the test to the strain with which the animals were immunized. This may occur even though a preliminary test with a large dose of the homologous strain 10-15 days before the heterologous test showed complete immunity. However, the results obtained in cross-immunity work are mainly a question of dosage, standardized if possible, for each organism. With a rigorous technic one can control to a considerable extent the many complicated factors and show relationships which could not be put in evidence by haphazard methods. As for the 8 California strains studied, judged by cross-immunity tests, all appear to be related to each other, some very closely, and some others, originating in areas about 450 miles apart, are undoubtedly identical. Only 1 strain at the time it came into my hands was markedly less virulent than the others.

The literature on the differentiation of species of spirochetes is too voluminous to review in this paper. The cytologic methods with immune serums apparently show differences to exist between strains which by the methods of passive or cross-immunity appear to be identical. The value of cross-immunity tests as a criterion of species relationship or identity, due to the variable results obtained by different workers and the inherent difficulties encountered, is seriously questioned by many.

Nicolle and Anderson⁹ believe that, because of the tendency of each spirochetal strain to individualize, there are no distinct species, and that this notion should be eliminated. On the other hand, the "pluralists," while admitting this tendency toward individualization as regards certain strains, believe that they do not go to the point of identity in all respects and therefore that species do exist. Nicolle and Anderson have given their criteria for the separation of the spirochetes of relapsing fever into groups giving less importance to the vector than to other characteristics. They state that the vector "is purely geographic and therefore fortuitous." This idea is not shared by Brumpt¹⁰ who believes that their identification should depend upon their transmission by the different species of vector. He was unable to transmit the Texas strains by any tick species tested other than *O. turicata* and conversely that *O. turicata* did not transmit experimentally by biting, *Sp. duttoni*, *Sp. venezuelensis*, nor *Sp. hispanicum*. He has, therefore, named the Texas strains and, provisionally, those of California, "*Spirochaeta turicatae* n. sp." This would seem, perhaps, rather premature, given the fact that *O. moubata* is capable of transmitting at least 5 spirochetal species and that most of these latter may be transmitted by 2 other tick species. The ability to transmit in nature and the adaptability of all the American ticks and other arthropods to the Texas and California strains have not been studied. While Kemp, Moursund, and Wright¹¹ have shown a strict adaptation between Texas strains and *O. turicata* they find that *Sp. novyi* is not transmitted in the laboratory by this tick. They¹² had previously shown by cytologic tests and the Pfeiffer phenomenon that *Sp. novyi* is identical with the Texas strains. They therefore consider that these latter do not constitute a new

species. They believe that "more stress could and should be placed on the serum tests, when these tests are made on solidly hyperimmunized animals, rather than on the specificity of the vector." I apologize if I have encroached upon the prerogatives of the epidemiologists in discussing this question before this section. My excuse is that the elucidation of the problem of the relationship between the American strains is so inextricably dependent upon results obtained in the laboratory.

I submit that we have a right to consider the results of the various workers and their conclusions in a critical spirit. Aside from the sources of error in maintaining spirochetal strains in a state of purity, it is well to remember the dictum of Nicolle and Anderson¹³ that "No invertebrate . . . can be considered as the transmitting agent of a disease if one has not recognized and demonstrated by what mechanism it transmits it in nature." That certain arthropods may or may not be shown in the laboratory to infect by biting does not necessarily prove that they are or are not the *usual* transmitters in nature, though they may or may not be. Likewise the infectiousness of emulsions of any given arthropod does not prove it to be in nature a vector of the disease by biting, though it may be.

The possibility or probability that biting insects other than lice and ticks may by adaptation become specific vectors is dependent upon ecological and other biological factors and the subject should elicit greater interest. Further work should be undertaken with California rodent fleas, as I am not yet convinced that my own infection may not have been due to these arthropods. The fact that my assistant was very ill with night sweats, chills, and high fever (blood not examined as he complained of bronchial symptoms), at the same time as my own infection is not without significance. We had both been

autopsying squirrels teeming with fleas and were severely bitten during 3 days. However, none of the animals, all of which were adults, proved to be infected with spirochetes.

CARRIER CONDITION

Whether the persistence of viable forms of spirochetes in the body and particularly in the brain of "recovered" animals is productive of a continual reinforcement of immune bodies has been a subject of much controversy. Kritchewski¹⁴ claims that neurotropic as distinct from somatropic races of spirochetes exist. Levaditi, Anderson, *et al.*^{15, 16} have shown that these persistent forms, generally invisible, cause lesions in the brain which have more than one analogy with those due to the neurotropic syphilitic virus. Their "encéphalite récurrentielle" began as early as 48 to 96 hours after the injection of *Sp. duttoni*. I² have already described the brain lesions of mice which had hemiplegia or other symptoms which might have been attributable to the injection of relapsing fever spirochetes. Though the relapsing fever therapy for general paralysis shows that no immunity exists in these cases I used several human serums showing a positive Wassermann reaction in protection experiments in mice against some California strains of relapsing fever. The results were all negative.

Authors differ as to whether spirochetes can be found in the brain when the blood is not infectious. Delanoë¹⁷ working with *Sp. hispanica* has stated that in the course of the disease the brain may be infectious but that this is never so unless the blood is also virulent. I⁸ have found this to be the case with California strains in all my experiments to determine this question.

Reactivation of latent infections—Some investigators claim that the antibodies of the blood stream present an

impenetrable barrier to the invasion of these forms, visible or invisible, which may be latent in the brain, bone-marrow or elsewhere in the body. Several workers, by the injection of *Trypanosoma brucei*, have reported the reappearance of spirochetes in the blood stream, in some cases as late as 5 months after the original infection. I¹⁸ have never been able by means of intercurrent infections, or typhoid, or other vaccines to obtain reinfections in recovered mice.

There is considerable doubt in my mind as to whether the carrier condition in this disease may be a source of great danger to man. However, we should not lose sight of the possibility of reactivation in the blood stream from various causes of those visible or invisible spirochetal forms which may have undergone little if any attenuation during the short period they may have remained in the bone-marrow or brain. A cryptic or abortive infection of the blood stream might result which, due to the presence of susceptible ectoparasites, might constitute a source of danger. Stitt¹⁹ is of the opinion that because second attacks in man usually do not produce relapses or sometimes even symptoms, such cases may become an ideal source of infection with lice or ticks. As a matter of fact, spirochetes have been found in the blood of man for very extended periods after "recovery" from infection (45 days in Madagascar and recently 5 months in San Francisco). Immunity in man, however, is apparently of short duration, Todd²⁰ having reported 2 natural infections in the same individual in a single winter. My own serum had no protective properties 8 months after my infection. It is fortunate that the urine, unlike the blood, does not constitute a source of danger in relapsing fever.

Golden Mantle ground squirrels (*Callospermophilus chrysodeirus*, *chrysodeirus* (Merriam))—Donkeys, horses,

sheep, goats, foxes, jackals, and some other wild animals, have cryptic infections. Many other species are found in nature to be infected. Of the squirrels and chipmunks surveyed in California no spirochetes have been isolated from the Golden Mantle ground squirrel (Dorothy Beck, personal communication). I¹⁸ made exhaustive studies of 5 adults of this species 1 month after capture. In none of them at various intervals was the blood infectious nor did the serum protect mice against the virulent strains with which I experimented. Many attempts to infect them with large doses by the conjunctival and intraperitoneal routes combined failed. Neither before (1 animal) nor after inoculation was the brain infectious. After inoculation the serums failed to protect mice against the strains inoculated. Whether these mature animals had an acquired immunity I do not know, but the study of the young of this species in the spring is indicated.*

As man is only an accidental host in California where massive louse infections do not exist, the subject of the carrier state, aside possibly from that in wild rodents, is only of academic interest.

COMMENT

Considering the presence in the Sierras of several species of ticks known to be vectors elsewhere of relapsing fever, that the transmission of spirochetes in ticks appears to be hereditary (Texas strains by *O. turicata*, Brumpt) and the widespread rodent reservoirs of the virus in our forests, the eradication of relapsing fever in California is well nigh hopeless. A blood examination should be made in all cases of fever of unknown etiology, especially if the patient had been in the mountains.

* Several workers have failed to demonstrate antibodies in the sera of patients subsequently proved by inoculation to be immune, and the sera of certain individual adult guinea pigs which were resistant to our strains did not protect mice nor contain other immune bodies.

Safety Speakers' Bureau

THE Metropolitan Chapter of the American Society of Safety Engineers, 29 West 39th Street, New York, announces the organization of a Speakers' Bureau consisting of 50 authori-

ties on accident prevention at work, on the street, and in the home. Speakers will be available without charge to industrial plants, schools, service clubs, women's organizations and other groups.

STANDING ORDERS FOR NURSE-TEACHERS

Associate Editor's Note: Since Dr. Wilson's Standing Orders for his school nurses at Evansville, Ind., was mentioned in the Nursing Section Notes (p. 80) of this *Journal* in January, 1934, a number of inquiries have come to the Associate Editor and Dr. Wilson from school men, school physicians, and health officers in widely separated parts of this country and Canada asking for copies of these Standing Orders.

Foreword by Charles C. Wilson, M.D., formerly Director of Health and Physical Education, Board of Education, Evansville, Ind., now serving in a similar capacity in Hartford, Conn.

"The health and physical education program in the public schools of Evansville, Ind., is a coördinated program of health service, physical education and health education. The entire program is under the Board of Education. As part of the health service program 5 nurse-teachers and 1 supervisory nurse-teacher are employed. This is in the proportion of 1 nurse-teacher to 2,500 pupils. The title nurse-teacher is used to emphasize the fact that an important function of the phase of the program is teaching. The nurse-teacher is really a teacher with nursing training. Her function is to use every possible procedure to further the education of pupils, parents, and teachers in the field of health and the prevention of sickness. The supervisor of nurse-teachers in Evansville is Florence Roller, R.N. The following are the Regulations and Standing Orders for nurse-teachers prepared by Miss Roller and approved by me."

I. Arrival at School

A. Upon arrival at school the nurse-teacher shall first sign the time book in

the principal's office. (The nurse-teacher shall make every effort to be at the school according to schedule and shall inform the principal, if possible, when unable to be there on time. If work at another school necessitates a change in schedule, that should be arranged for with the principal and the supervisor.)

B. Time for home visits may be taken from the school period scheduled when indicated.

II. Duties of Nurse-Teacher

A. At school clinic

1. A definite signal, arranged for by the principal, shall be used to announce to the teachers that the nurse-teacher is ready for clinic. At this time all children needing health care shall be sent to the room assigned for this purpose. Each case should be made educational and the children should be taught and encouraged to give first aid when possible. The nurse-teacher inspects the children, gives advice or treatment, takes a temperature when indicated, or recommends exclusion. She should give the teacher any necessary information concerning the child. Be sure that teacher and principal clearly understand the purpose of your clinic.

2. Keeps First Aid Cabinet in order and well supplied.

3. Have some one responsible for materials when nurse is not present.

B. Assisting doctors with physical examinations

1. Previous to examinations, vision and hearing should be tested and recorded on health cards. The date, age, grade, height, and present weight should also be filled in.

2. Be responsible for letters sent out urging parents to be present at time of examinations.

3. Assist with clinical work at time of examination as necessary. You may interview parents concerning correction of defects, etc., may give vision or hearing tests, verify weight record, etc., for benefit of parents.

4. Endeavor to make the examinations as private as possible. Also see that children are undressed to waist for examination.

5. Notify parents of findings and recommendations made during physical examination.

a. Give slip to parent at time of examination.

b. Send notices home as soon as possible after examination.

c. Home visits, if possible, made to homes of all children with defects, whose parents are not present at examination. Make home visit on all cases with heart or lung condition marked 2 or 3 the same day examination is made.

d. Make out Health Score Charts for teachers following the examination.

e. Tabulate the results of examinations for each school and make reports to supervisor.

C. Work with parents

1. Coöperate with P. T. A. as much as possible by keeping them informed as to the work being done in the school and giving information and reports to Health Chairman.

2. Circumstances permitting, urge parents to call at school for consultations concerning their children's health.

D. Home visits

1. Each home visit should be purposeful and educational, not only for the individual but for the family as a whole. Keep your relations with the family on a friendly basis even though you do not accomplish your objective.

a. Explain the need and urge correction of physical defects.

b. Make arrangements for such corrections as must be made through the free or partially pay service.

c. Investigate known cases of illness where no medical care is being given. Arrange for medical and nursing care to be given, if needed.

d. Make post-operative visits where nurse-teacher has arranged for operation.

e. Learn home conditions of children and secure parents' coöperation.

f. Make an investigation of any case of tuberculosis, contact or suspect.

g. Give necessary demonstrations of:

Ventilation of sleeping room

Shampoo

Gargling

Proper cleansing of ear

Dressing or compress

Treatment for pediculosis, impetigo, scabies

E. Make routine room inspections when indicated

1. For communicable disease, pediculi, etc., instruct the teachers in method of inspection and encourage them to give the daily room inspection. The inspection may be conducted as follows: The nurse explains to the teachers her reason for visiting the room. She stands with her back to a window. The children pass before her about 2 feet apart, giving her an opportunity to observe their condition. Instruct pupils to show the palms and back of hands with fingers spread and sleeves pushed up as far as possible. Lift hair showing ear and scalp behind ears, also forehead. Draw down their lower eye lids, throw back their heads so that edges of nostrils may be seen, open mouth so that throat may be examined (individual tongue depressors used when necessary). The nurse-teacher should avoid handling children but should ask the teacher to take the names of any children whom she wishes to have examined more closely. After finishing inspection, these children should be cared for individually in the clinic.

2. Exclusions—The nurse-teacher shall, in the absence of the physician, recommend the exclusion of any pupil who, in her judgment, shows signs or symptoms of a communicable disease. If the principal desires, she shall make out the exclusion blank in duplicate, giving one to the child and filing the other in the office. She should notify the Board of Health of any suspicious reportable disease. Date of re-admittance should be entered on stub of exclusion book when child returns. (Principal should appoint some one to care for these matters in nurse's absence.)

F. When special examination of a child is indicated, leave with the school clerk the following information: Child's name, school, grade, teacher's name, and reason for examination.

SUPPLIES FOR SCHOOL FIRST AID
CABINETS

Alcohol 70%
 Tr. iodine 3½%
 Mercurochrome 2%
 Oil of cloves
 Vaseline
 Zn. oxide ointment
 Ammoniated mercury 2%
 Tr. green soap
 Aromatic spirits of ammonia
 2 in. gauze bandages
 1 in. gauze bandages
 Roll adhesive
 Sterile gauze roll
 Cotton
 Toothpicks
 Thermometer
 Scissors
 Needles
 Paper bags for waste
 Eye chart
 Communicable disease chart

STANDING ORDERS FOR USE OF SUPPLIES

Refer cases to family physician when in your judgment his care is needed. *Nurse-teacher must not assume responsibility for the care of infections.* Application of drugs should be made with toothpick cotton swab or cotton pledget, fresh ones used for each application. Dressings showing good home care should not be removed if in good condition unless the nurse feels it is for the best interest of the child. Apply sterile dressings as needed but use as economically as possible. Use a piece of sterile gauze to cover injury and use roller bandage to hold in place unless adhesive will serve the purpose equally well.

NOTE: All dressings, applicators, tongue depressors must be well wrapped in paper before being put in waste paper basket.

In case of serious injury make every effort to get in touch with family as they should take the responsibility for securing medical service. Give simple first aid until physician is secured or family takes child over.

Fetus and Ringworm—Scrub with tincture of green soap, paint with tincture of iodine. The next day and each day until healed, apply 2 per cent ammoniated mercury ointment.

Impetigo—Remove crusts with tr. of green soap, apply 2 per cent ammoniated mercury.

Bandage if possible. Exclude cases which might endanger others. Give parents printed slip outlining treatment, if parents are unable to obtain medical advice.

Discharging Ears—Cleanse only. Swab with cotton.

Pediculosis—Exclude until following day all children having live pediculi. Those with nits only may remain in school if nurse is satisfied that condition is being properly treated. Follow up with home visit if necessary to get condition corrected. Give parents printed slip outlining treatment.

Scabies—Exclude for 3 days. If case is neglected, make a home visit to secure correction. If family is unable to care for it, give printed slip of instructions.

Cuts or Scratches—Swab with tr. of iodine or mercurochrome.

Cold Sores—Apply zinc oxide.

Poison Ivy—Zinc ointment dressing.

Burns—Apply vaseline lightly. Bandage as necessary.

Boils—Apply sterile gauze dressing. Spread lightly with vaseline.

Dog Bites—Let bleed freely. Apply sterile dressing. Report name and address of person bitten. Report name and address of dog's owner to Board of Health. Use influence to have dog secured *alive* for examination.

Toothache—Apply oil of cloves with cotton on toothpick.

Earache—Urge care by family doctor.

Foreign Substance in Eye—Use small cotton swab moistened in clean water or flush eye with boric solution, using cotton pledget.

Splinters—Use forceps or needle sterilized in alcohol. (Clean with green soap and alcohol before putting away.)

Care of Thermometer—Rinse with water before putting in mouth. After removing, wipe with cotton, wash with green soap, scrubbing vigorously, wipe with cotton, scrub with alcohol and dry before replacing in case.

The above suggestions for care are offered for use in those cases where children show signs of neglect. The above suggestion should not be carried out in any case where the parents are receiving or are able to obtain medical care. Urge home care. Treat neglected cases only. First aid treatment for accidents and injuries occurring at school is the function of the nurse-teacher. Treatment of other conditions is a responsibility of the parents and the family physician.

Current Mortality Releases*

STEWART G. THOMPSON, D.P.H., F.A.P.H.A.

Director, Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

THE records centralized in the various bureaus of vital statistics are valuable in proportion to the use which is made of them. The universal policy has been to emphasize the importance of the records as legal documents and for the preparation of statistical tabulations which are usually old. This paper is not intended to minimize the legal or statistical value of the records but rather to point out another very important use which is sometimes overlooked—the first-aid which they may give to health workers in checking epidemics and arresting deaths from preventable causes.

There has been an unnecessary loss of human life due to procrastination or negligence in disseminating promptly the information available in the various vital statistics departments. The U. S. Bureau of the Census furnishes current releases for various states and weekly releases for 69 cities. The U. S. Public Health Service publishes weekly current releases not only for the United States but also for foreign countries. This material is of tremendous value and provides the health worker a picture of what has taken place. These releases and others which are too numerous to mention have their place and provide a very necessary and valuable part of the public health program. The major part of the material in the releases to which I have just

referred originated in the offices of the registration executives and while the information is important to the state and to the United States in observing what has already happened, there appears to be entirely overlooked the use that may first be made by local or smaller units.

Morbidity reports, if complete, are of much more value in epidemiological work than are the mortality records. In most states, however, morbidity reports are very incomplete, and warnings of epidemics are often first discovered through the mortality records. The state registration executive, therefore, has a definite responsibility and an important part in cooperating with health officials.

In efficient state registration, the first prerequisite is to have a very close working basis with the state health officer or state commissioner of health. The vital statistics department is not faithfully performing its duty until the state health officer has been informed currently of what is happening in the state as pictured by the vital statistics records. Some states wait for the U. S. Bureau of the Census tabulations before they really know what has happened within their own boundaries. In many other instances, the tabulations are made annually by the states or current releases given quarterly and semi-annually in tabular form by city or county units. This is not real cooperation with the state health officer.

In many states, the vital statistics department does not receive sufficient appropriation, is not rated in importance

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

with other departments of the state board of health, but is rather considered just a bookkeeping department. This under-rating of a vital statistics department is largely the fault of the registration executive himself. The volume of routine work necessary to build a vital statistics department and keep it going very often brings those in charge so close to their task that they overlook entirely a wonderful opportunity to give out information promptly that will contribute a real and important asset in the hands of the health officials for stamping out epidemics and curtailing the loss of life from preventable causes.

It is not enough to inform the state health officer as to the number of deaths in the state or in a county from a preventable cause or from a group of preventable causes. He needs more definite information for quick action. For example, Escambia County, Fla., had an unusually large number of deaths from typhoid fever for a number of years. Statistical tables showing the number of deaths from this cause, by counties, had been published at various times but the high average for this particular county as compared with other counties did not receive attention. A spot map was, therefore, prepared indicating the exact location in the county of each death from typhoid fever and the information was placed in the hands of the state health officer who, in turn, directed an investigation to be made immediately. The result was very gratifying. For a decade, there had been an average of 10 deaths a year from typhoid fever in this particular county. The year after the investigation was completed and the source of infection discovered, there were only 3 deaths from typhoid fever in the entire county, and so far this year not a single death.

It was found many years ago that Taylor County, Fla., which is in a malaria district, had the highest death rate from this cause of any county in

the state. From 1919 to 1929 there was an average of 15 deaths annually. An anti-malaria campaign was undertaken by the State Board of Health, with the coöperation of the U. S. Public Health Service, and later a regular county health unit put into operation. The result was spectacular in that there has been an average of only 5 deaths from malaria in that county during the past 4 years, which more than justified the expenditure of time and money.

It is only natural that a state registration executive should often be tempted to neglect the study of current data in order to do the more spectacular or pleasant work. Workers in counties having well organized health programs, with few deaths from preventable causes, are making a real contribution to their citizens, with little praise or commendation. On the other hand, the county to which I have just referred is talked about all over the state for the wonderful work and splendid results accomplished. There is very little comment made about a railroad company which has introduced block signals and other important equipment for the prevention of railroad accidents. When a railroad wreck occurs and the engineer performs some unusual heroic feat, his name is in the headlines of every paper because he took a personal risk in order to save the lives of his passengers. If the train service had been efficient enough to prevent the accident, the passengers would have slept in their berths, the train would have arrived at its destination, and the results taken for granted. This, in a way, illustrates the difference between the spectacular results obtained from research work in vital statistics and the control of preventable deaths by the prompt use of information taken from current releases.

Little reference has been made in this paper to current releases as an index for the health worker as their value is

accepted without question. Those who have first access to original data have a real responsibility. Prompt action is necessary for the control of epidemics. The records received in a bureau of

vital statistics are carrier-pigeons bringing advance information. A dove carrying a sprig of foliage may not attract particular attention but Noah in his Ark grasped the import of its message.

Certified Milk in Two Pennsylvania Counties

MORE than 2,000 samples of certified milk were examined during the 10-year period from 1923 to 1932 by the milk control laboratory serving 9 suburban boroughs and first class townships near Philadelphia in Montgomery and Delaware Counties, Pa.

In an elaborate statistical analysis of the data on these samples, which were distributed uniformly by months and fairly so by years, a number of interesting facts are brought out. Ninety per cent of the samples were found to contain not over 10,000 colonies of bacteria per c.c., and those exceeding the standard were most numerous in the summer months. Ninety-five per cent of the samples

showed the standard butter fat content of 3.5 per cent or more, although out of the total of 2,248 samples one had 7.3 per cent, and another 13.0 per cent butter fat. Only a few of these milks revealed skimming or the presence of visible dirt.

The author points out what is recognized by health officials, that while most certified milks are consistently of excellent sanitary quality, some are occasionally below standard. He does not, however, indicate how many farms, or what individual farms, may have been responsible for lowering the general average of excellence.—David Wilbur Horn. *A Survey of Certified Milks. Hahnemannian Month.*, June, 1934.

Endemic Typhus

J. N. BAKER, M.D., F.A.P.H.A., JAMES G. McALPINE, Ph.D.

AND

D. G. GILL, M.D., D.P.H.

Alabama State Department of Health, Montgomery, Ala.

THE world-wide distribution of the various forms of typhus fever with its increasing incidence in various countries is causing more and more attention to be directed toward this disease. During 1933 large numbers of cases were reported from Asia, Africa, the United States, Peru, Mexico, the Balkan States, Portugal, Poland,

fatality rate is of negligible importance in the United States. Occasionally it appears among immigrants, but it has never gained a permanent foothold here. On the other hand, Brill's disease or endemic typhus has shown a marked increase in our Southern States during the past 2 years.

From Table I it will be seen that the

TABLE I
TYPHUS FEVER INCIDENCE IN SOUTHERN STATES
1928-1933

	1928	1929	1930	1931	1932	1933
Florida	0	48	39	28	42	54
Georgia	48	57	134	127	308	625
Alabama	59	72	67	80	237	823
Louisiana	0	1	0	1	17	11
Texas	5	8	13	43	227	398

and Lithuania. According to the *Medical Officer*,¹ Great Britain, France, Germany, and New Zealand are the only countries which escaped typhus during the early months of 1933.

Old-world typhus with its high

morbidity rates for Alabama, Georgia, and Texas have been especially high in 1932 and 1933. The number of cases in Louisiana and Florida has been small, and in Mississippi very few have been reported. For 1932 and 1933 Egypt

had more than its normal number of cases, and in Poland and in the Balkan States typhus has been rapidly increasing since 1931. Table II gives some idea of the incidence of this disease for the past 6 years in various countries.

EPIDEMIOLOGY

From earliest times epidemic typhus has been closely connected with filth and human misery. It has been called jail fever, ship fever, and famine fever. Wherever the standard of living has been materially lowered, typhus has almost invariably made its appearance, and this obvious connection had caused many speculations concerning its etiology and method of conveyance.

Otto² (1909) from observations made among army troops believed that vermin acted as vectors. Nicolle, Comte, and Conseil³ (1909) proved that the body louse could transmit epidemic typhus among experimental animals. Soon their work was confirmed by Ricketts and Wilder⁴ (1910), Anderson and Goldberger⁵ (1912), da Rocha Lima⁶ (1916), and others. Since then it has been demonstrated that the spread of epidemic typhus may be prevented if the louse is destroyed. Epidemiological data show that outbreaks are most common in the late winter and early spring when louse infestation is the highest.

In 1898 Brill⁷ recognized in the United States a type of fever which, resembling typhoid, gave a negative Widal reaction. He^{8,9} demonstrated its similarity to typhus, but showed that it was milder and less contagious, only one case as a rule being found in a household. He reported that it was most prevalent during the fall instead of late winter or spring. In 1912, Anderson and Goldberger¹⁰ proved that Brill's disease was immunologically identical with Mexican typhus or tabardillo. Naturally this led to the belief that it was louse-borne.

Maxcy¹¹ (1926) in an extensive epidemiological study of Brill's disease or endemic typhus was at a loss to explain its non-contagious character and its seasonal incidence if he assumed that the louse was the vector. Since he noticed that a larger number of cases appeared among persons handling food-stuffs, he was inclined to believe that rats and mice might be the reservoirs and that the disease was carried to man by fleas, mites or ticks. He emphasized the fact that Brill's disease shows no preference for the lower strata of society and bears no relation to lousiness. The next step was taken when Dyer, Rumreich, and Badger¹² (1931) were able to recover the virus of Brill's disease from rat fleas which had been found in typhus foci.

Rumreich¹³ (1933) has pointed out that until 1931 ". . . there was, in spite of Maxcy's fundamental work, much confusion in regard to the probable vector of endemic typhus, and a variety of insects and arachnids were suspected by different workers. Among these vectors were the tropical rat mite, common North American chigger, the body louse, the head louse, the Anopheles mosquito, the bed-bug and the tick. It is now obvious that much of this chaos was due to the fact that two distinct clinical entities were being confused, and for this reason Maxcy's observations were not more widely accepted." The work of Rumreich, Dyer, and Badger¹⁴ (1931) definitely proved that there are in Eastern and Southern United States 2 diseases which are related both etiologically and serologically. One of these is endemic typhus which is transmitted to man by the rat flea; the other is Rocky Mountain spotted fever which is carried by the tick. Although ticks may be infected by intrarectal injection of the typhus virus, the fact remains that, as Dyer¹⁵ (1933) states, "the isolation of spotted fever cases from the true typhus group

TABLE III
SEASONAL DISTRIBUTION OF CASES
Alabama, 1926-1933

	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.

removed all epidemiological evidence that the tick was acting as a vector of typhus fever in the country."

ENDEMIC TYPHUS IN ALABAMA

Typhus fever was first recognized in Alabama in 1922 when a series of cases giving a positive Weil-Felix Reaction were reported by Maxcy and Havens.¹⁶ From that time until 1932 cases continued to be reported—60 to 80 cases each year. The disease has been confined almost exclusively to South and Southeast Alabama, with certain localities showing cases year after year. In 1932 there was a very sharp increase in incidence—237 cases with 11 deaths as

compared to 80 cases and 4 deaths the preceding year. This increase continued during 1933 when the cases reached 823 and the deaths 35. From the urban centers the disease spread and much of the incidence is now in purely rural areas and among people who could not have obtained their infection except at home. Association with food establishments is still an important factor in urban cases.

The seasonal occurrence has remained constant during all this time with the summer and fall months accounting for most of the cases. This is contrary to the experience with the epidemic type of the disease.

TABLE IV
DISTRIBUTION OF 1,029 CASES OF TYPHUS FEVER BY RACE, SEX, AND AGE
Alabama, 1932-1933

Age	White		Colored		Total	
	Male	Female	Male	Female	Male	Female
0-4 years	4	10	0	0	4	10
5-9 "	20	15	1	1	21	16
10-14 "	43	31	2	2	45	33
15-19 "	67	24	3	0	70	24
20-24 "	46	26	1	4	47	30
25-34 "	105	51	10	11	115	62
35-44 "	117	52	7	3	124	55
45-54 "	74	46	8	4	82	50
55-64 "	42	20	4	2	46	22
65-74 "	21	11	0	1	21	12
75 and over	3	2	0	0	3	2
Not Stated	66	56	9	4	75	60
Total	655	344	45	32	653	376

Race, Sex, and Age—Maxcy¹¹ called attention to the relative freedom of the negro from the infection. This holds true, but not to the same extent, since there have been 77 cases reported among colored in the past 2 years. In the 21 counties most concerned the negro population is 45 per cent of the total so that the attack rate among them is only one-tenth that of the white. Males continue to predominate particularly among the whites, and adults are most affected. With the extension of the disease into rural areas, and with the infection being acquired at home, more women and children are being exposed. Table IV shows the distribution of 1,029 cases reported during 1932 and 1933 in which race, sex, and age were given.

Diagnosis—These cases were seen by a number of physicians, but the clinical appearance was sufficiently characteristic in most instances to be readily recognized. During 1933 the laboratories of the State Health Department examined 1,445 specimens of which 461 were positive for the Weil-Felix Reaction, while an additional 81 were classed as doubtful. This compares with 149 positive tests in 1932, 63 in 1931, and 61 in 1930.

Fatality—During 1932 and 1933 there were reported 46 deaths from typhus fever. Based on 1,060 cases re-

ported for these years, this is a case fatality rate of 4.3 per cent, an annual death rate of 0.84 per 100,000 population. This fatality was lower than that for cases reported prior to this period. In the 498 cases reported in 1922-1931, inclusive, there were 38 deaths, a fatality rate of 7.6 per cent. No doubt, the morbidity was reported more completely during the last 2 years and this is a partial explanation of the decrease in the fatality rate. It is apparent that there has been no increase in the fatality with the increased incidence.

Whereas, 73 per cent of the cases in Alabama during the last 2 years were under 45 years of age, only 35 per cent of the deaths occurred in this age period. As shown in Table V, the fatality rate varied greatly with age, being less than 2 per cent for cases under 45 years; 5 to 7 per cent between the ages of 45 and 64 years, and approximately 30 per cent for persons above 65 years of age.

These conclusions are based on the fatality rate for white cases, in so far as the number of colored cases, by age, was too small to warrant analysis. The fatality rate for the colored cases was 11.7 against 3.8 for whites. That the higher fatality rate for negroes may be due, to a considerable extent, to less complete recognition and registration of cases for this group is possible.

TABLE V
CASE FATALITY, TYPHUS FEVER, ALABAMA
(Based on 1,029 Cases)
1932-1933

	Cases *				Deaths				Deaths per 100 Cases			
	White		Colored		White		Colored		White		Colored

All ages	608	344	45	32	25	12	7	2	4.1	3.5	15.5	6.3

* Unspecified Ages Distributed

(a) Number of cases too small to make significant rates

It should be noted that when 2 or more causes are given on the death certificate typhus fever is preferred over all other causes except cholera, plague, yellow fever, and deaths from violence. A study of the death certificates for these deaths reveals that on only 11 was typhus fever the only cause given. The most frequent contributory cause was pneumonia, in 14 instances; nephritis in 9; myocarditis in 6; apoplexy in 4; and all other causes, 8. In some instances more than one of these conditions were also noted on the death certificate. A contributing factor to this higher fatality in the higher ages is the fact that these persons were already suffering from a chronic heart or nephritis condition which would have made them poor risks for any infectious disease. In uncomplicated cases the case fatality for endemic typhus is low.

Control—During the past 2 years the disease reached such proportions that it became a serious public health problem. The definite incrimination of rats and rat-fleas as sources of infection naturally pointed to rat destruction as the most feasible means of attack. The area of Alabama most seriously infected corresponds roughly to the peanut growing area so that the rat population was probably large. Nearly all homes visited reported manifest rat infestation. During 1933 many of the towns in the area concerned inaugurated rat control programs—combining poisoning and trapping in most instances. With the inauguration of the CWA work program a larger, widespread program superseded the local efforts and a serious attempt at rat destruction was undertaken in some 21 counties. It is estimated by the Biological Survey that almost 4,000,000 rats were destroyed in this project which closed with the discontinuance of the Civil Works Administration program.

It is too early to determine the effect this wholesale slaughter will have on the

typhus incidence during 1934, but the early months of the year have not shown the expected incidence.

At present studies are being conducted as to other possible reservoirs of infection in nature, but the rat is probably the greatest offender. Eradication is almost impossible, but continued effort will materially lessen his menace to the health of the people.

DISCUSSION

Endemic typhus fever, or Brill's disease, has during the past 2 years become a serious problem in Alabama and some other southern states. From foci in certain cities the disease has spread to rural areas and is now widespread.

The original observations of Maxcy as to race, sex, age, and seasonal distribution have been largely confirmed.

The case fatality rate for uncomplicated endemic typhus is low. Much of the mortality is in the older age groups. There has not been an increase in case mortality rates with the increasing morbidity.

The work of Maxcy¹¹ and of Dyer, Rumreich, and Badger¹² has shown that the reservoir of infection is in the rat and that transmission is by the rat-flea. The mild winter climate, plentiful food supply, and absence of rat-proofing in buildings are all conducive to heavy rat infestation.

An attempt at control of typhus in man through rat eradication was carried out during the early months of 1934 with the effects still to be determined.

Evidently typhus fever has secured a firm foothold in Alabama and is going to require a continuous control program.

Hop-Picking

AS the occupation is healthy, and financially is reasonably recompensed, there is a holiday element in it which appeals to the city dwellers. If the summer is warm and comparatively dry, it is a real outing for the East End Londoners, but if it is wet the immigration is shorn of much of its attractiveness for, even under the most favorable weather conditions, the health authorities find it extremely difficult to house the invaders, notwithstanding the large number of permanent corrugated iron camps which are dotted all over the areas. In South West Kent alone, and here I borrow my figures from Dr. Galbraith's reports, there are 386 hop farms with 11,548 huts to accommodate the 67,000 pickers who arrive every summer. In many of the camps it is more or less a gipsy life which is led, but pure water is carried into all the camps both for drinking needs and hygienic

requirements; the cleaning of camps and the removal of litter have to be attended to, but, despite all efforts, overcrowding is a blot on the family and social life of the camps. . . . One consequence of handling the hops, or as the result of friction of the skin against the catkins and leaves of the plant is the occurrence of an inflammation of the skin. The dermatitis, or "hop rash" as it is called, and due to an irritant evolved from the plant, is mostly observed on the arms. The inflammation may affect the eyes, giving rise to "hoppers' eye," or there occurs what is called "hoppers' gout," an inflammation of joints or a synovitis mainly of the wrists, and probably caused by the repeated and fatiguing movements of the joints in picking.—Sir Thomas Oliver. Disease and Disaster Traceable to Vegetable Sources. *J. State Med.*, July, 1934, pp. 421-422.

THE PASADENA MEETING

THE 63rd Annual Meeting of the Association will go down in history as one of the most successful ever held. It will be remembered that the special reason for selecting California this year was because it was the 5th anniversary of the foundation of our Western Branch, and our meeting was a con-joint one with that organization. Every arrangement possible was made for our accommodation, entertainment, and pleasure. The hospitality of the people of California was unbounded, and here in the name of the Association we wish to express to our hosts our appreciation.

The scientific sessions were well thought out; there were excellent programs; and attendance was very good. It may be invidious to select certain features, and we possibly would not do so except for the interest of the entire Western Coast as well as throughout the country in the epidemic of poliomyelitis. We had a session devoted entirely to the consideration of the outbreak of this disease in California generally, and Southern California particularly. Every seat in the vast room was filled.

Another notable feature was the session of the Western Branch at which Dr. Walter H. Brown was inducted as president. All the members of the parent organization were invited to attend. It was a dinner session and every seat was well filled, it being necessary to bring in extra tables. The first General Session, on Monday night, at which the President's address was given, was one of the largest meetings, not only of this session but of any session which the writer remembers. This was held in the Main Hall of the Civic Auditorium, a magnificent amphitheater, in which the acoustics were really remarkable. The speakers could be clearly heard in the most remote seats, a feature we would like to recommend widely to the architects of buildings used for such purposes.

Among the special features were excursions through the beautiful orange groves

in which Pasadena is situated. Among the older members, an excursion to Hollywood attracted particular attention, and doubtless the home-town papers will have accounts of meetings with Will Rogers and Mae West.

Wonderful roads have been constructed along the coast, so that one can drive from the extreme southern point up as far as Santa Barbara just along the edge of the ocean, giving a panorama of high mountains which one can almost touch from the car window on one side, and the ocean on the other. The increase in population along the coast has been surprising, and the beaches are thronged by thousands practically every day.

When the invitation was given to visit California we were promised a warm reception—Pasadena has more than made good. However, one can cool off by a dip in the ocean all the year round.

A special feature was the visit to the Huntington Library which, although usually closed at this season, was opened for the Association. It contains the largest collection of Gainsboroughs in the United States. Outstanding among the treasures is the famous Blue Boy. The Library has also acquired a notable collection of early English books, proclamations, orders, and so forth, on public health, which shows that England was very far advanced before the decadent era which ended with Chadwick.

For the fourth year, the general meeting was preceded by the Health Education Institute, under the direction of Dr. Iago Galdston. The attendance was the largest of any year, 208 students having been registered, approximately 80 per cent of whom were from California, the rest from other states and territories. The Institute opened on the morning of August 31, and was continued mornings and afternoons, closing Monday morning.

It will be remembered that the New York Central Railroad arranged for a special train to accommodate representatives from eastern United States and Canada. More than 100 delegates made the trip across the continent. Stops were made at various points such as at the World's Fair in Chicago and at the Grand Canyon. Fortunately the inter-tribal meeting of the Indians was being held at Gallup, N. M., affording the unique opportunity of seeing the Indian ceremonies. The train was met in Pasadena by representatives of the local committee and Dr. J. D. Dunshee, the Health Officer of the state. On the return trip the excursionists were entertained in San Francisco by Dr. Geiger, Director of Health, by Dr. Sippy, at Stockton and Lodi, Dr. True, at Sacramento, Dr. Beatty of Salt Lake City, and Dr. Jaffa at Denver. Altogether the trip on the special train was unusually comfortable.

The scientific exhibits were of unusual interest. Prominent among these was the exhibit of The Deutsches Hygiene Museum. This was accompanied by Dr. Bruno Gebhard, as custodian, and was sent to this country by the Museum which is at Dresden. This was a most gracious action on the part of this organization, and Dr. Gebhard made many friends by his unfailing courtesy and clear demonstrations. The exhibits of Pasadena and Los Angeles were worthy of special notice. The engineering features of the water supply and sewage disposal of Pasadena were particularly well represented. Various excursions to the water shed and plants, afforded to health officers and engineers an opportunity to see them in operation. The State Board of Health had its travelling Plague Unit, fully equipped on hand, and examination of ground squirrels was constantly demonstrated.

The annual banquet held Wednesday evening at the Hotel Huntington was

largely attended. Great interest was shown in the address by J. W. O'Conner, M.R.C.S. from Columbia University, New York.

A notable feature of all the public meetings was the remarkable interest of the public, evidence of their interest and health consciousness. We regret that our constituent countries were not represented by larger delegations, but those who were present were of the highest quality. From Mexico came Dr. Francisco P. Miranda; from Canada, Dr. Robert E. Wodehouse; and Dr. Med. Bruno Gebhard from Germany. Mr. Aime Cousineau and Dr. S. Boucher of Canada were also present.

The words used are entirely inadequate in describing the good features of the Pasadena meeting and the reception given by the warm hearted inhabitants of Southern California.

PUBLIC HEALTH EDUCATION*

FROM PEOPLE WHO DON'T KNOW YOU

SEEK opportunities for meeting people who do not know you as the executive—people who belong to the audiences you have been reaching. Seek to learn what they think of various features of the effort. Did they respond to any of the appeals? Did they go to anything? Did they read anything? Do they remember any of the arguments? Did any of the printed matter reach them? Are they with you or 'agin' you or your project?

Budget Exhausted but Not the Demand—More about *Salud y Sanidad* mentioned under "We Salute Colombia!" in the August, 1934, issue:

The address is: Departamento Nacional de Higiene, Sección de Saneamiento Rural, Apartado 2508, Bogotá. The phrase "Para la Vulgarización y Propaganda de la Higiene" is simply a legend defining the purpose of the publication, although we trust that it is neither "vulgar" nor "propaganda," in the English sense.

This little health magazine has had a reception which has really surprised us. We started in 1932 with 6,000 copies and soon found that even by distributing it only to persons who requested it either by letter or in person that the issue was inadequate. We increased the number to 10,000 and later to 15,000, which exhausts our budget but not the demand. It is used in many schools as a text, and we have received a great many flattering comments. In fact, people take it so seriously that it keeps us worried with the fear that errors or disputable material may slip into it. Our effort is to make it scientifically sound first and then simplify the style. The Director of the publication, Sr. Ricardo Bonilla, has achieved a style which is really remarkable for its simplicity and clarity, and that, of course, has been all important in making it a success. We have tried to avoid the sentimental manner of "writing down" to our readers which so

often happens when physicians or public health men try to prepare "propaganda."

George Bevier, M.D.

"Hygeia" for July, 1934—From time to time we list the main contents of *Hygeia*, the outstanding health publication for the general public. We thus supplement the historical record, provided in this department of the *Journal*, of current thought and activities in public health education. We hope also to remind our readers of a variety of easily available source material, and of topics which may merit consideration in state and local publicity.

A Sensible Vacation (editorial); Hazardous summer days; Skin cancer—actual and potential; Your children's eyes; Skeletons not in closets (pictures of Century of Progress exhibits); The campaign against corpulence; Manhattan spastic clinic; Save your child's teeth; Committee acceptance of fruit juices; Some famous victims of smallpox; The story behind the little purple stamp (federal government meat inspection); Refrigerator facts; The parathyroid glands; The hot weather problem in infant and child feeding; The bedbug; Training for athletics and health; Your summer vacation; I want to know: mysterious fluids; New books on health; Questions and answers; School and Health, including A new approach to health education; The challenge of vacation; Health examinations as basis of health education; Clinics now come in classrooms; A bibliography for solving health education prob-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

lems; New health books for teachers and pupils.

One Is Free—One You Pay For— Happenings and developments in connection with the current activities of the Milbank Memorial Fund will be reported in the future in the *News Digest*, which it is planned will supplement the Milbank Memorial Fund *Quarterly* in spreading information regarding work in the fields of public health, medical care, and social welfare. While the subscription to the *Quarterly* is \$1 a year, the *News Digest* is sent without charge to professional workers in the fields to which the Fund directs its attention (40 Wall St., New York, N. Y.).

Reading References on Child Health and Health Education—The following mimeographed annotated lists are supplied upon request (single copies) to American Child Health Assn., 50 West 50th St., New York, N. Y.:

"Some Recent Contributions to Health Education." A brief list compiled as a service to instructors giving courses in health education. 3 pages.

"Supplementary Reading Materials for Health Education. Grades I-IX." Interesting types of reading suitable for classroom libraries. 6 pages.

"Health Education in Elementary Schools." Brief bibliography for classroom teachers. 6 pages.

"Some References on Child Care and Training for those conducting Child Care Classes in Secondary Schools or Parent-Teacher Groups." 5 pages.

"Some References on the School Lunch." 3 pages.

Riding a Hobby Horse—Public health education will be the better for the riding of hobbies by the workers in public health education. This thought prompts us to mention "Care and Feeding of Hobby Horses," by Earnest Elmo Calkins. This pamphlet of 112 pages "contains 700 suggestions for the use of leisure time" and the bibliography

lists 1,500 books and pamphlets for hobby riders. But it is more than lists. Note two chapter headings: "Getting More Joy Out of Life," and "What is Play?" Leisure League, 30 Rockefeller Plaza, New York. 25 cents.

For the "Women's Crusade"—This fall and winter many non-public health agencies will participate in community chest and other joint money raising efforts. It is anticipated that there will be increased coöperation by large groups of volunteer interpreters, in many cases under the name of the Women's Crusade.

The essence of this effort as a successful supplement to other promotion and publicity efforts is three-fold:

1. Organization and leadership
2. Preparation of usable material
3. Development of methods

Many helps and suggestions will reach the chests through Community Chests and Councils, Graybar Bldg., New York, N. Y., to which you may write for first-hand information if local interest is delayed.

National, state, and local health agencies may help the whole local effort, and better further the part of the health locals by working out ideas and materials suitable and effective for use by the volunteer interpreters.

A new approach would be the use of stillfilms or filmslides. The pocket projector as offered by two manufacturers is no larger than many of the folding cameras and can be used on any light circuit in home, office, or club. Forty or 50 "frames," picture or text units, equivalent to lantern slides, may be thrown on a wall or white card. The audience may be one person, or a group gathered in a home, club, or office.

A big value of the method is that it provides easy talking material for demonstrator and members of the audience.

By having a single projector and one copy of a film, a volunteer, or several

volunteers, could reach 2, 3, or 4 small groups in an afternoon. This could be repeated 4 or 5 days a week through a considerable period.

The amateur movie affords another valuable medium for the fall and winter campaigns. Now is the time to get pictures of camps and any other outdoor health activities.

A third little used medium is the marionette or puppet show. Both have been used successfully by health agencies. Neither has as yet been fully developed to present community, family, or individual health problems in a simple, straightforward way. Either promises considerable usefulness in reaching several types of audiences.

The three new media are described in order of difficulty in getting them into action. All three have the splendid value of offering usable material which can be handled by interested volunteers. All are comparatively inexpensive, and adaptable for use throughout the year, and are effective for groups not so easily reached by other means.

The editor of this department will be glad to tell you where to get full information about any or all of the above.

"Stay Away from Pasadena"—

A "warning" issue of *News Letter* of Western Branch, A.P.H.A. (Aug., 1934), was addressed to members of the different sections. We reprint two paragraphs, looking toward the 1935 meeting.

You'll be disappointed in the meeting if you belong to any of the following groups:

Public Health Educators are satisfied with their efforts to teach health in schools, health departments, among the general public, and in industry; are satisfied that their school medical and nursing program is a supreme educational experience for the child; know why some educational efforts succeed and others fail; get the utmost coöperation from their daily newspapers and radio broadcasting stations; know how to reduce dental caries in a school system 75 per cent through educational methods alone; know the tech-

nique of selling the health department to the public; know how to discriminate between good and poor publicity material.

A New Type of "Demonstration"

—A demonstration in which there are no outside funds, no outside supervision, no increased or exceptional staff members, no "the-world-is-watching-you" appeal.

As a complement to the undoubted values of the public health demonstration projects of recent years we propose for adult health education a different procedure.

The demonstration will start with the present staff and the current available funds of the department or association, local or state.

The one outside factor will be the enlistment of some of the "best minds" in the health education field to help think out the project.

Who is interested in this type of demonstration?

Health Education in August, 1934, *Journal*—The following articles are of interest to readers of this department:

"The Use of Laymen in Official Public Health Nursing Programs," by Dowling

"Qualifications and Training of Local Health Officers," by Parran & Griswold

"Public Health in Tudor England," by Larkey

"Medical Supervision in the Public Schools," by Gould. Includes paragraph summarizing the "Health Education Program"

For More than Hospitals—All institutional forms of health and medical care could benefit by application of the practical outline offered in "Hospital Ethics, Publicity, and Public Relations," by Dr. W. T. MacEachern. This appears in *Bulletin*, American Hospital Association, 18 E. Division St., Chicago,

Ill. Mention is made of ready-made press material, motion pictures, etc., available for hospital use.

In the opening paragraphs the author tries as others have done to offer a precise definition of "publicity" to find synonymous terms. There doesn't seem to be any satisfactory escape from words which in the course of a long life take on some unpleasant associations. The bad company so often trails right along with the new words. And the meanings of most words are determined by the individual who uses them, as well as by the individual who reads them. Hence we have no adequate word term for the diverse functions of health education and publicity (or health education or publicity, or health education publicity).

MAGAZINE ARTICLES

To quote: to write about.

"An Adventurer in the Conquest of Disease," by Theodore Roosevelt, Jr. *Saturday Review*, 25 W. 4th St., New York, N. Y. July 7, 1934. 10 cents. An appreciative review of "A Soldier in Science," by Bailey K. Ashford.

FOR EDUCATION OR REFERENCE

Usually where no price is given *single specimen* copies will be sent upon request.

"Average Age of Death." State Board of Health, Madison, Wis. An effective bar diagram by years, 1903 to 1933; 40.8 years to 55.4 years, with several decreases indicated.

"A List of Publications—Jan. to June, 1934." U. S. Public Health Service, Washington, D. C. Free.

For poison ivy the best help we have

discovered is "Poison Ivy and Poison Sumac and Their Eradication," a Farmer Bulletin of the Dept. of Agriculture. It covers more points as to the nature, control, prevention, and simple handling of these poisons than is otherwise available in one publication, and it is more specific on more points than is usual. Dated May, 1929.

"Instruction in the Effects of Alcohol and Tobacco," by J. F. Rogers, Office of Education. Renewed interest and present status; difficulties and dangers; information sources. 8 pages. Supt. of Documents, Washington, D. C. 5 cents.

"Warning on Poliomyelitis" and "How to Prevent Poliomyelitis" are two conversations broadcast by Los Angeles County Health Dept., Los Angeles, Calif. 5 and 7 mimeographed pages, supplemented by an 8-page booklet.

From State Dept. of Public Health, Boston, Mass.:

"Aids to Bowel Movement." 4 pages.

"Cooking for Health." 16 pages. Recipes and sample menus.

"The Difference between Tweedledum and Tweedledee." 4 pages. Radio talk which mentions "those words, gonorrhea and syphilis, that people and newspapers and magazines seem to fear so much."

"Food Customs from Abroad." 16 pages. Concise background statements; typical day's menu; food habits; bibliography—for French Canadian, Irish, Italians, Jewish, Near East, Polish, Portuguese.

"Rabies." 4 pages.

"Activities of the Department." 4 pages.

"Vitamins." 2 pages.

"Your Baby's First Teeth." 4 pages.

"Your Second Teeth." 2 pages.

Reprints from U. S. Children's Bureau, Washington, D. C.:

"Child Health 1933-1934," by M. M. Eliot, M.D. Critical review from Children's Bureau and Dept. of Pediatrics, Yale School of Medicine.

"The Need for a More Adequate Program of Maternal Care," by F. C. Rothert, M.D.

From Metropolitan Life Insurance Co., New York, San Francisco, and Ottawa:

"Vaccination Protects You Against Smallpox." 4 page folder.

"The Junior Safety Volunteer." 16 pages. "Tells how persons are frequently hurt on the street and in their homes, and how such accidents can be prevented," with "blank pages, too, for making a list of conditions which you think are unsafe and in need of correction."

"Health Programs in Professional Schools for Teachers." 44 pages. Includes "The Participation Approach in Health Education," "Coöperation of the Staff for Health Education," and "The Health of Students and Faculty."

"The Health of the Teacher." June, 1934, issue of *Health Bulletin for Teachers*.

BOOKS AND REPORTS

The Principles of Heating and Ventilation—By *H. M. Vernon, M.A., M.D.* London: *Edward Arnold & Co.*, 1934. 232 pp. Price, \$5.00.

This work by an expert who has devoted his life to the subject of heating and ventilating and whose works in connection with the Institution of Heating and Ventilating Engineers, the Technical Advisory Board of the National Institute of Industrial Psychology, and particularly as Investigator for the Industrial Health Research Board, is most timely indeed, and should have a large and appreciative reception in America as it may be said to summarize the latest views from a Britisher's standpoint. As a matter of fact, there are undoubtedly more references to research findings and committee reports of American origin than British, but the author has dwelt especially on the relations of the subject to health and physiological functions, which is a welcome innovation in an extensive field of publications dwelling essentially upon the engineering phases. The latter, however, are adequately covered as to principles and better practices, and make up most of the discussion.

The chapter headings involve environmental conditions controlling the heat loss from the human body; heat loss from buildings; heating by means of open fires; heating by hot water, steam pipes, and radiators; low temperature radiant heating; low temperature heating by electricity; the necessity for ventilation; natural ventilation; mechanical ventilation and warm air heating; control of humidity; and air conditioning and special ventilation in industry. Numerous tables and some 50 figures, all very well selected and pre-

pared, are included as well as a good index.

The book particularly discusses the practical aspect of various theories, reduces most technical information to the grasp of the intelligent lay reader who might be interested, and carries annotations at the bottom of the pages to sources of information which the author approves and which are practically all of recent date. The book is meant to be of especial value to architects, factory inspectors, health officials, health and sanitary officials. Notably, the importance of considering effective radiation as well as effective temperature, temperature gradients from floor to ceiling, insulation, new forms of heating, and instruments for use in interpreting atmospheric conditions, are excellently handled. One wishes that terms which may bewilder the less informed were specifically defined, that comment on lower limits of fresh air quantity were extended in view of the rapid spread of cooling devices, and that the author had announced his own conclusions more often after summarizing the facts selected from many sources.

Still, one can read between the lines that the author considers many current practices, *e.g.*, attempting to draw a rational deduction from all of the elements entering into heat loss from buildings, as possible of integration for practical purposes, and thereby explaining failures so noticeable everywhere in ventilation installations of the present day. In a country like America in which this field has been so largely run away with by the commercial interests involved, this book is a source of welcome enlightenment indeed.

The publishers are also to be com-

plimented upon placing in compact form, easy access, and good binding, the material comprised between the covers.

It would also be well to read at the same time the little volume put out in 1931, *School Ventilation, Principles and Practices*, representing the final contribution of the New York Commission on Ventilation. The present work endorses most of the Commission's findings, while it adds considerable in the way of new thought and experiences.

EMERY R. HAYHURST

Children of the New Day—By Katherine Glover and Evelyn Dewey. *New York: Appleton-Century, 1934.* 432 pp. Price, \$2.25.

A satisfactory method is employed in this book to interpret for parents and guardians the technical reports of the White House Conference on Child Health and Protection. It is presented along lines similar to the volumes appearing in the Century Childhood Library. The main sections of the White House Conference reports are set forth in simple, non-technical language and easy style. The "discussion points" at the end of each chapter present the major findings of the various committees of the Conference.

The book should popularize and extend the information assembled in the more detailed and formidable reports. It offers no easy solution of the problems it presents, but concludes that "perhaps the only real gift we can pass on to children today is awareness."

RICHARD A. BOLT

The Science of Work—By Morris S. Viteles. *New York: Norton, 1934.* 442 pp. Price, \$4.00.

This work is essentially a recasting in more popular form of a previous text, *Industrial Psychology*, by the same author. The earlier book was technical and exhaustive, but the present one

avoids most of the technical terminology, minimizes tables, resorts more widely to graphic presentation, and relegates the footnotes to an appendix. One other contrast with similar books is a somewhat broader point of view, responsive to problems of the present economic situation. For instance, the desirability of training workers in groups of related jobs to facilitate readjustment if the job is displaced by machine or depression; and the psychological problems of possibly adjusting 10,000,000 white collar workers to manual jobs in the next 10 years; again, where experiments with shortened hours have increased total output, the implications regarding government efforts to shorten hours to increase jobs.

After two chapters from the historical standpoint comes the discussion of employment problems. The procedure of job analysis is outlined, with forms and charts. The use of employment tests are standardized by comparison with ability in the job. The method is illustrated by numerous, brief, well selected examples. The author wisely cautions against the use of such tests by "amateurs."

An outstanding aspect of accidents is the existence of individual susceptibility and the possibility of measuring this by tests. Of equal importance is the study of the individual accident case from a clinical standpoint. Typical case-studies are included. Factors such as fatigue, ventilation, and attitude are discussed. The author recommends "the replacement of a fatalistic doctrine of 'chance' by a dynamic policy of individual mental hygiene in accident prevention."

Training considers practising only correct methods; training on the job rather than in the classroom; initial emphasis on accuracy rather than speed; distributed rather than intensive practice; and practice curves as a guide and for motivation. The author

presents recent data on the psychology of old age, and the possibilities of training older and more experienced workers.

To relieve fatigue by adjustment of hours is complicated by the worker's tendency to adopt a "congenial" pace. The optimal length of day will vary with the industry and even with the job. Efficiency is defined in terms of least physical cost and minimum feelings of fatigue and dissatisfaction—a commendably broad point of view. Experiments are cited on calorimetry during work, rest pauses, posture, intensity of illumination and air conditioning.

Regarding monotony, the author varies from the extreme social viewpoint and believes that only a small minority crave creative experience, while other adjustments are usually possible. Financial incentives have been somewhat overemphasized and we must consider the total personality of the worker. Employees often restrict production in the face of financial incentive. The rôle of "instincts" has likewise been overemphasized. A rather sound approach is to study motives and incentives experimentally just as with accident cases.

Then we have the possibilities of salvaging misfits with personality difficulties rather than discharging them. The approach is a clinical study of individual cases. Attention is called to the effect of long unemployment upon the individual's attitude.

The importance of supervision is considered. When turnover is negligible some supervisors become "real bosses" and loyalty hits a new low. Constructive measures include scientific selection of supervisors, systematic training (centered around case material), and a general "lead" rather than "drive" philosophy of management. Employee representation must be preceded by education as to its purpose and significance.

The author stresses repeatedly the concern of the industrial psychologist

with the happiness and contentment of the worker as well as his efficiency. Where necessary the worker should sacrifice economic to human values. Moreover he should be concerned not only with pleasure in work but with enjoyment of hours outside of work—in short, the entire environment.

The reviewer has no particularly adverse criticism. Attempting to cover a large field, the book obviously must touch points lightly and must select rigorously from the large amount of material available. Such selection is well made, and illustrative material is concrete and to the point. Business readers will be interested in the various "forms" provided as those for job specification.

The book obviously is written down to the level of the non-technical reader but remains systematic. It is enlivened by simple line drawings in somewhat cartoon style. Even some of the charts are so embellished. The author might well have carried this slightly humorous flavor into portions of the text. The work is well done and attains its objective. The reader will find it a very good introduction to the field of industrial psychology.

HAROLD E. BURTT

Lord Lister: The Discoverer of Antiseptic Surgery—By C. J. S. Thompson, M.B.E. London: John Bale, Sons & Danielsson, Ltd., 1934. 99 pp. Price, \$1.75.

This charming little book has been written to fill what has long been recognized as a need; namely, a short biography for the use of students and general readers. The author has consulted Sir Rickman J. Godlee's biography of Lord Lister, which is justly regarded as one of the great biographies of all time.

The book contains only 93 pages of text. It is written in good style, gives all of the main facts which the public

needs to know of Lord Lister, and ends with a short chapter on "Humanity's Debt to Lister," in which is quoted Sir Frederick Treves's statement: "He is the greatest benefactor of mankind which any age has known. His life and work will live for ever."

The book can be thoroughly recommended, and we wish for it a wide circulation among the profession as well as the laity. Only education can stop some of the innumerable cults which pretend to heal diseases, but which in the main do tremendous damage to the cause of public health.

MAZÛCK P. RAVENEL

A Soldier in Science: The Autobiography of Bailey K. Ashford. *With a foreword by Major General M. W. Ireland.* New York: William Morrow & Co., 1934. 425 pp. (Ill.) Price, \$3.50.

One picks up an autobiography by a contemporary man of science with a question. Can a man write about his own work with sufficient modesty and yet make an interesting story? Dr. Ashford has achieved a difficult task. Here is the story of experiences just as Colonel Ashford would relate them to his friends in moments of leisure and when all are in the mood for exchanging stories about the War, the laboratory, the campaign for hookworm, or how Puerto Rico got its School of Tropical Medicine.

Just as, through such talk one enjoys the experience of making the acquaintance of a man, so you make the acquaintance of Colonel Ashford. It is such a human story that the reader soon feels he has caught this interesting personality in his laboratory; when he will talk about his Sprue cases, he shows you his beautiful *Monilia* cultures, and he describes the objections of the scientific world to accepting his point of view on the relation of *Monilia psilosis* to tropical sprue.

How the Army sent him here and there and how each time he got orders to return to Puerto Rico is a narrative full of such triumphs, humor, and interest that the reader hurries in from one incident to another.

One of the most interesting chapters is the battle for recognition of the fact that the profound anemia of the Puerto Rican peasant was caused by hookworm, and how he spread the news throughout the Island that the anemia "was being cured for the first time in the memory of man—was being cured by certain mysterious little glass balls, together with purges." The clamor that went up to continue this work was so formidable "that gentlemen in frock coats who took no interest whatsoever in such things nervously consented to any proposition that would keep their constituents quiet and satisfied." Here is a story of public health progress that will intrigue any administrator.

Former Surgeon-General Ireland in a foreword reports, "The University of Cairo, conferring an honorary degree upon Colonel Ashford several years ago, introduced him as "Prophet of Tropical Medicine in the New World, who has rendered incalculable services to Science and Mankind." Such services he has no doubt rendered but a story so real and true to this soldier in science will give inspiration and courage to many who will continue to carry on long after Colonel Ashford has inoculated his last guinea pig. Romance and ideals of medical science are portrayed through the richness of experience of Colonel Ashford's life to date.

HAROLD H. MITCHELL

National Quarantine Service, Series IV—*Edited by Wu Lien-Teh, Director, and C. Y. Wu, Senior Quarantine Officer, 1933.*

In the preface to the fourth annual report of the National Quarantine Service of China, the editors state that

it has been their object to make this book a reliable guide to the manifold activities of the Service, and, at the same time, having in mind their obligations as a public body toward lay organizations, such as the mercantile and shipping interests in the country, to present a readable and not too technical account of that section of the work which is most closely connected with the commercial world. In this endeavor they have succeeded admirably.

The volume opens with a series of original articles on plague and cholera, which are not only of absorbing interest, but are of scientific and historical value as well, and should appeal strongly to research workers and quarantine executives. The next section is devoted to a series of well written and informative special articles dealing with the recent public health activities in Shanghai and with the transactions of the Central Cholera Bureau. There is also included an account of the fourth annual dinner of the National Quarantine Service, with a number of the speeches delivered during the evening. Then follow reports of the Administrative, Boarding, Fumigation, and Medical Services Division, and of the branch stations at Amoy, Chinwangtao, Tientsin, Taku-Tangku, Wuhan (Hankow), and Canton, all of which should especially make a ready appeal to non-medical readers interested in port health development in China. The book is brought to a conclusion by the insertion of a list of the personnel of the Quarantine Service at headquarters and at the branch stations.

The report shows that, notwithstanding the political and economic disorder which prevailed in China during the year, steady improvement was made in all branches of the Service. Two of the more outstanding achievements of the year, in addition to the maintenance of the work of medical inspection and fumigation on an efficient basis, were

the continuation of the rat-flea survey of Chinese ports which was begun in 1931, and the inauguration, in 1933, of systematic experiments upon the occurrence and viability of cholera and related vibrios in Shanghai waters. Comprehensive accounts are given of the results so far obtained.

A plan to produce a series of monographs on the infectious diseases commonly occurring in China was launched toward the end of the year by the publication of the first volume—a manual on cholera, compiled by senior members of the Quarantine Service. While this monograph was written especially for the medical profession of China, it covers a wide field and should be generally useful to the medical profession throughout the Far East and also to anyone engaged in an extensive study of the cholera problem.

During the year, a site was acquired for a new quarantine station at Shanghai, and plans were perfected for the erection of up-to-date buildings to house the various activities. Upon the completion of this station, the quarantine facilities at Shanghai are expected to be adequate for practically any emergency.

In spite of the great difficulties under which the Chinese National Quarantine Service has labored since its inauguration in 1930, it has carried out many helpful reforms and has greatly enlarged the scope of its activities.

Research has been persistently prosecuted into many problems intimately affecting the public health of the country. At the same time, regular contact has been maintained with international organizations such as the International Office of Public Hygiene and the Health Section of the League of Nations. The year 1933 saw the realization of efforts to place on a satisfactory basis the collection and dissemination of epidemiological information relating to Chinese ports. Weekly

bulletins of communicable diseases were distributed regularly to port and city health authorities in China and neighboring countries.

The editors have contrived to give a great deal of information in compact form, without over-elaboration; yet everywhere the sentences flow smoothly and make pleasant reading. One color plate and 27 half-tone illustrations are attractive features of the book, while numerous charts and tables add to its value. The report is cordially recommended to the readers for whom it is designed.

F. A. CARMELIA

The Savannah Cook Book. *A Collection of Old Fashioned Receipts from Colonial Kitchens—Collected and Edited by Harriet Ross Colquitt, with an introduction by Ogden Nash. New York: Farrar & Rinehart, 1934. 186 pp. Price, \$2.00.*

Now, good digestion wait on
appetite,
And Health on both!

During the last few years, in a number of our cities which are famous for their cooks and cookery, there have arisen loyal citizens, mostly women, who have collected the "receipts" for which the particular city is famous. There is no pretense that this book is written in the interest of public health, and probably the authors would not pass very outstanding examinations on balanced rations, vitamins, etc.

We have no wish to force a point, but believe that the researches of Cannon, Pavloff, and others, have demonstrated the value of the esthetic point of view in the preparation and service of foods. From the economic standpoint it may be emphasized that rice, which furnishes the main article of food for approximately one-third of the population of the world, is not sufficiently eaten, possibly because it is not properly prepared, in a large part of the United States. The book before us is especially

strong in methods for preparing sea foods and rice dishes, and can be heartily recommended.

MAZÏCK P. RAVENEL

You Must Relax—*By Edmund Jacobson, M.D. New York: McGraw-Hill, 1934. 201 pp. Price, \$1.50.*

The author's attempt is to explain—to the layman—"how to relax while you are working, playing, or resting."

The general thesis of this text is apparently: "In the rush of the present day, man has in part forgotten how to live."

After discussing various types of tense persons, and the causes of over-active nerves, the author takes up the various means of artificially soothing the nervous system; drugs, massage, hydrotherapy, change of environment, diet, and rest.

He then launches into his main idea—cultivated relaxation. Relaxation is a habit and like any habit may be cultivated by regular daily practice. Among others, there are chapters on "How to Relax Lying Down," "How to Relax while Active," "Relaxing Worry," "The Quest for Sleep," and on "Indigestion and Colitis and on Blood Pressure as related to fatigue of the nervous system—over-emotion."

This is a worthwhile book which it will repay both laymen and physicians to read carefully. It brings to the fore the close relationship between agitation and other mental states, and such health factors as intestinal upsets, blood pressure, and nutritional states, and prescribes a method whereby the one afflicted may bring about his own relief.

CHARLES H. KEENE

Manual of Nursery School Practice
—*By Iowa Child Welfare Research Station. Bulletin of the State University of Iowa, New Series, No. 730, March 10, 1934. Price, \$1.00.*
This is a well conceived and executed

manual of the development and present status of preschool practice at the Iowa Child Welfare Research Station in Iowa City. Following several introductory chapters on the nursery school idea and preschool education, a detailed description is given of housing, equipment, personnel, and technics used at the Iowa Station. These are illustrated beautifully and appropriately with photographs taken on the premises. The reading material is arranged conveniently for reference.

Its completeness leaves no doubt as to what the research projects are and how they are being pursued in detail. Typical daily schedules are given for each age group. A complete set of record blanks is reproduced. The "developmental record" should prove of especial interest to those engaged in nursery school work. Ten full pages of excellent reference on nursery schools and nursery education complete the bulletin.

This informative and helpful manual is recommended highly to all those interested in preschool education and in the nursery school movement.

RICHARD A. BOLT

Military Medical Manual—Produced for The Military Surgeon by The National Service Publishing Company, Washington, D. C., 1934. 774 pp. Price, \$4.50.

Adequate preparedness for national defense is one of the best preventives of war. Since, however, the human race seems to display a biological tendency toward conflict, war may be inevitable. In a world fairly seething with international distrust, belligerency, and arrogance, military preparedness is a positive safeguard, by making possible a more effective defense.

In time of war, no branch of the military forces is more important than the army medical department, the mission of which is to prevent disease and con-

serve health, as well as to care for the sick and wounded.

The information needed by officers of the Medical Department of the U. S. Army, which includes members of the Medical, Sanitary, Dental, Veterinary, and Medical Administrative Corps, is set forth in a comprehensive manner in this excellent manual, which should be owned and studied by every reserve officer in these services. In the 17 parts of this well printed book will be found useful and interesting material on military policies, administration, organization, law, hygiene, sanitation, hospitalization, evacuation, and medico-military science.

As Surgeon General Robert U. Patterson states in a brief foreword, *The Military Surgeon* has performed a real service in making available this volume covering the whole range of subjects in which patriotic members of the medical and public health professions should be proficient.

JAMES A. TOBEY

The Road to Adolescence—By Dr. Joseph Garland. Cambridge, Mass.: Harvard University Press, 1934. Price, \$2.50.

This is a book that deserves wide reading. It is a successful attempt to bring together in a usable form for those concerned with growing youth the more important results from long experience and recent studies. The author evidently has first-hand knowledge of his subject and is familiar with the latest contributions.

All through the book runs a vein of conservative common sense; new ideas and suggestions are wisely evaluated, and the conclusions expressed in a terse and interesting style.

It is gratifying to see the importance that is placed upon the kind of material our children receive through inheritance, and upon the value of eugenics, a science which, as yet, is receiving too little practical attention.

Subsequent chapters discuss the anatomy and physiology of the growing child, the care of the body, nutrition and diet, the recognition and care of sickness, vaccines and serums, first aid to the injured, home, school and camp, and special problems in education, with a final word—"As the twig is bent," in which the environment of the home and the responsibility of parents for developing the latent possibilities of their children are tactfully but vigorously stated. "We cannot turn the potato into a lily or the oak into a willow," says the author, "our province is to make our potatoes the best in the countryside and our oak the sturdiest in the forest."

The various factors that play a part in this complicated problem—the home, the school, private or public, occasion-

ally beginning with nursery school and kindergarten, special classes for special problems, the value of proper play and exercise—are all discussed with that wisdom which only results from intimate knowledge. One regrets that the value of the midday rest for all children under 7 years is implied but not emphasized. Dr. Garland's book discourages fads in child care and training but is replete with many facts and suggestions which should be of real assistance to those who wish to be guided wisely in this difficult field.

A job of each generation is to produce children of the best possible material and then to prepare them adequately in body and mind for their future tasks. To this great endeavor in our day this book is a helpful contribution.

J. H. MASON KNOX, JR.

BOOKS RECEIVED

DIPHTHERIA—PAST AND PRESENT. By J. Graham Forbes. London: John Bale, Sons & Danielsson, 1932. 832 pp. Price, \$15.00.

INFLUENZA. Part II. Annals of the Pickett-Thompson Research Laboratory. By David Thomson and Robert Thomson. Baltimore: Williams & Wilkins, 1934. 1557 pp. Price, \$17.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Controlling Contagion—Preventive measures to be used against scarlet fever, diphtheria, measles and whooping cough are all covered in this interesting British symposium.

BANKS, H. S., *et al.* Control of the Common Infectious Diseases. *Pub. Health* 47, 11:348 (Aug.), 1934.

Protecting Against Tetanus—Alum precipitated tetanus toxoid in 2 doses of 1 c.c. given 3 months apart produces a state of immunity which affords protection if a third 1 c.c. dose is given at the time of injury.

BERGEY, D. H. Active Immunization Against Tetanus Infection With Tetanus Toxoid. *J. Infect. Dis.* 55, 1:72 (July-Aug.), 1934.

Showing Up the Supposed Cancer Increase—Studied by age groups in New York City, it appears that there has been no increase of "visible" cancer (skin, breast, buccal cavity, female genitals), in the last three decades. From this it may be inferred that the increase in "invisible" cancer is due to better diagnosis.

BOLDUAN, C., and WEINER, L. Is Cancer More Prevalent? *Am. J. Cancer* 21:4:825 (Aug.), 1934.

Experiments in Health Insurance—Trials and tribulations of projects in mutual medical service in California are reported with every evidence of impartiality.

BROWN, P. K. California's Medical Mix-Up. *Survey Graphic* 23, 9:429 (Sept.), 1934.

Tuberculous Children — Among 6,000 New York children admitted to

hospitals, 13 per cent of the boys and 15 per cent of the girls reacted positively to tuberculin: among 2,000 attending "well" children clinics there were about the same percentage of reactors; while among 6,000 attending tuberculosis clinics half were reactors. Rates in other cities are compared.

DROLET, G. J. The Incidence of Tuberculous Infection among Children in New York City. *Am. Rev. Tuberc.* 30, 1:1 (July), 1934.

It Goes for Us too—Four British authorities answer the question: Are We Satisfied with the Results of Antenatal Care? The net answer seems to be: No, but the outlook is hopeful.

FAIRBAIRN, J. S., *et al.* Are We Satisfied with the Results of Antenatal Care? *Brit. M. J.* 3839:193 (Aug. 4), 1934.

Trichinosis Increases in New York—A 5 year study including 166 cases of trichinosis emphasizes anew the extreme importance of adequate cooking of pork and pork products.

FRANT, S. Five Years' Experience with Trichinosis in New York City. *Pub. Health Rep.* 49, 30:869 (July 27), 1934.

Polio Comes Early to California—Steps taken to deal with a California outbreak of poliomyelitis are outlined in this preliminary report. One finding noted is that affected individuals may be found in all age groups. The term "infantile" is inappropriate.

GEIGER, J. C., *et al.* Acute Anterior Poliomyelitis. *J.A.M.A.* 103, 5:342 (Aug. 4), 1934.

Decent Rivers—Progress is reported in the movement to enact laws to prevent stream pollution, and stream con-

trol agencies are functioning in ever wider areas—so it is claimed. May they continue to prosper!

HOSKINS, J. K. Stream Pollution Control. Water Works Eng. 87, 16:870 (Aug.), 1934.

Prompt Diphtheria Immunization

—That alum precipitated toxoid immunizes quickly against diphtheria is evidenced by this study in which better than 90 per cent of the subjects were rendered Schick negative from 40 to 90 days after treatment with 1 c.c. dose.

KELLER, A. E., and LEATHERS, W. S. Alum Precipitated Diphtheria Toxoid. J.A.M.A. 103, 7:479 (Aug. 18), 1934.

More Health Insurance—Methods for providing medical services for everybody are discussed in stimulating detail. Answers to these questions are proposed: who shall be covered? what services shall be given? how will they be paid for? how shall the service be administered?

KINGSBURY, J. A. Health Insurance for American People. Pub. Health Nurs. 26, 8:423 (Aug.), 1934.

Milk as a Vehicle for Vitamin D

—Crystalline vitamin D added to milk was more potent as an antirachitic factor than when administered dissolved in oil. Antirachitic agents must be given directly to nursing infants; feeding the mother cannot be relied upon as a method of administration.

LEWIS, J. M. Clinical Experience with Vitamin D Milk. New York State J. Med. 34, 15:685 (Aug. 1), 1934.

When Health Education Is Neglected—Immunization against diphtheria and/or smallpox vaccination

when done are in most instances medical services rendered without the accompaniment of effective health education. The results are obvious.

PALMER, G. T., and DERRYBERRY, M. Medical and Public Health Attitude toward Smallpox Vaccination and Diphtheria Immunization. New Eng. J. Med. 211, 9:413 (Aug. 30), 1934.

Influencing Human Behavior—

Among Ontario children a wide variety of health habits was discovered in respect to eating wholesome meals, good sleeping habits, and the like. The beneficent effects of health education were not pronounced.

PHAIR, J. T. Survey of Health Habits among School Age Children. Canad. Pub. Health J. 25, 8:380 (Aug.), 1934.

What Expectant Mothers Need—

In a country-wide sampling and study of maternal deaths it was found that a third were caused by abortions. Of those mothers that might have had prenatal care, more than half had none, a fourth had poor care, only an eighth had reasonably good care.

ROTHERT, F. C. The Need for a More Adequate Program of Maternal Care. Pub. Health Nurs. 26, 8:407 (Aug.), 1934.

For Lady Nicotine's Devotees—

Cigarette smoking produces a marked drop in surface temperature of fingers and toes, slows the blood flow in the capillaries. Nicotine is one of the toxic factors, but carbon monoxide is not. It will be interesting to see how these findings will be used in cigarette advertising.

WRIGHT, I. S., and MOFFAT, D. The Effects of Tobacco on the Peripheral Vascular System. J.A.M.A. 103, 5:318 (Aug. 4), 1934.

ASSOCIATION NEWS

OFFICERS, 1934-1935

President, EUGENE L. BISHOP, M.D., Nashville, Tenn.

President-elect, WALTER H. BROWN, M.D., Palo Alto, Calif.

First Vice-President, J. C. GEIGER, M.D., San Francisco, Calif.

Second Vice-President, JAMES ROBERTS, M.D., Hamilton, Ont., Canada

Third Vice-President, FRANCISCO DE P. MIRANDA, Mexico City, Mexico

Treasurer, LOUIS I. DUBLIN, Ph.D., New York, N. Y.

Executive Secretary, KENDALL EMERSON, M.D., New York, N. Y.

Chairman of Executive Board, THOMAS PARRAN, JR., M.D., Albany, N. Y.

1935 MEETING IN MILWAUKEE

EUGENE L. BISHOP, M.D., PRESIDENT

WALTER H. BROWN, M.D., PRESIDENT-ELECT

WITH the Sixty-third Annual Meeting in Pasadena, Calif., Haven Emerson M.D., retired from the office of President of the A.P.H.A., which office he has so ably filled during the past year. E. L. Bishop, M.D., who was President-Elect, became President,

to serve for the year 1934-1935. For two years preceding Dr. Bishop's election as President-Elect, he served as Chairman of the Executive Board. It will be remembered that he was instrumental in the organization of the Southern Branch A.P.H.A. He is Ten-

Eugene L. Bishop, M.D.

Walter H. Brown, M.D.

nessee State Commissioner of Public Health, and now serving also as Director of Health of the Tennessee Valley Authority, Knoxville, Tenn. Dr. Bishop has been a member of the A.P.H.A. since 1921, and a Fellow since 1924. He is a Life Member.

The new President-Elect is Walter H. Brown, M.D. of Palo Alto, Calif. He is one of a small group of public health workers actively engaged in promoting a well organized public health program in the Far West. He is President of the Western Branch A.P.H.A., which celebrated its Fifth Anniversary by a joint meeting with the parent Association in Pasadena. Dr. Brown will bring to his duties a sympathetic understanding of the problems and needs of the active health worker, based upon a broad experience as an administrator and teacher.

Dr. Brown was graduated from Jefferson Medical College, Philadelphia, in 1906; he practised medicine in Richlandtown, Bucks Co., Pa., 1906-1913;

was graduated from Harvard-M.I.T. School for Health Officers in 1914; was Epidemiologist of Massachusetts State Department of Public Health, 1914-1915; Health Officer of Bridgeport, Conn., 1916-1919; Associate Director of Health Service, American Red Cross in Washington, D. C., 1919-1920; with the Rockefeller Foundation 1920-1921, assigned to the Commission for Prevention of Tuberculosis in France; Director of Child Health Demonstration, 1921-1925, conducted at Mansfield, Ohio, under the direction of the National Child Health Council, on a grant by the American Red Cross; with the Commonwealth Fund of New York City, 1925-1927, assigned to the Directorship of the Child Health Demonstration in Marion Co., Ohio; and since 1927, has been Professor of Hygiene, Leland Stanford University, Palo Alto, Calif.

Dr. Brown has been a member of the A.P.H.A. since 1915, and a Fellow since 1922.

RESOLUTION ON THE DEATH OF DR. FREDERICK W. SEARS

DR. Frederick W. Sears of Syracuse, New York, died suddenly in Butte, Montana, on August 30, 1934, while on his way to attend the meeting of the Association. Dr. Sears has been a Charter Fellow of the A.P.H.A. since 1922 and a member since 1914, and took an active part in its affairs. At the height of a successful career, Dr. Sears gave up his large surgical practice in order to devote his full time to service in the New York State Department of Health.

During his 20 years as State Sanitary Supervisor and District State Officer, he not only showed rare administrative talents and teaching ability but also became known for his important contributions to preventive medicine. He was a pioneer in diphtheria immunization, a

procedure demonstrated to be practical and effective by Dr. Sears, long before its general adoption, and carried on by him until his death with the collection of one of the largest known series of individual records.

Therefore **BE IT RESOLVED**, that the members of the A.P.H.A. record their official recognition of the distinguished service to public health, rendered by Dr. Sears, at the same time expressing their deep sorrow in the loss of a valued member and a friend of unfailing kindness and great personal charm; and be it further

RESOLVED, that this resolution be spread upon the records of this meeting, and that it be transmitted to Dr. Sears' family.

SEDGWICK MEMORIAL MEDAL

AT the Pasadena meeting the Sedgwick Memorial Medal for distinguished service in public health was awarded Edwin Oakes Jordan, Ph.D., Department of Hygiene and Bacteriology, University of Chicago. Dr. Jordan is a graduate of M.I.T., 1888, and served as Chief Assistant Biologist of the Massachusetts State Board of Health immediately after graduation. He was Lecturer in Biology at M.I.T. at the same time, being thus associated with Prof. William Thompson Sedgwick in whose name the medal is granted.

Dr. Jordan was called to the University of Chicago in 1892, when the university was founded. He was an associate in the department of anatomy where he began the teaching of bacteriology, instructor, assistant professor, associate professor, and finally professor of bacteriology. He held his departmental chair in bacteriology from 1907 and the chairmanship of the Department of Hygiene and Bacteriology from 1914 until a few years ago. He was then appointed to a Distinguished

Service Professorship which he held until he retired from formal teaching and administration in the University of Chicago. He has many scientific papers to his credit. His textbook of *General Bacteriology*, probably his best known work, was published in 1908. In 1917 appeared *Food Poisoning*, in 1924, *A Pioneer in Public Health—William Thompson Sedgwick* of which Dr. Jordan was one of the three authors. In 1927 he published *Epidemic Influenza*. In 1928 *The Newer Knowledge of Bacteriology and Immunology* came out, by Dr. Jordan and Professor Falk. He was a member of the International Health Board of the Rockefeller Foundation from 1920 to 1926.

In recent years Dr. Jordan has been a leading member of the Board of Health of Chicago. The full list of activities, connections, and notable services is a very long one. He has been a member of the A.P.H.A. since 1899 and became a Charter Fellow in 1922. He did much work in the development of the Standard Methods of A.P.H.A.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Councils will follow.

Health Officers Section

Clarence I. Drummond, M.D., Court House, Medford, Ore., County Health Officer
 Frank H. Garriss, M.D., Windsor, N. C., Bertie County Health Officer
 David B. Tuholski, M.D., 93 Main St., Brockton, Mass., Health Officer
 Louis S. Welty, M.D., Denton, Md., Deputy State and County Health Officer

Laboratory Section

Branch J. Aymond, M.D., Rapides Parish Health Unit, Alexandria, La., Acting Director
 Theodore D. Beckwith, Ph.D., 405 Hilgard Ave., Los Angeles, Calif., Professor of Bacteriology, University of California

William N. Berg, Ph.D., 104 Fifth Ave., New York, N. Y., formerly with Bureau of Animal Industry, Washington, D. C.
 George E. Coleman, 609 Hot Springs Road, Santa Barbara, Calif., Research Associate in Medicine, Hooper Foundation, University of California
 Gerard Laviano, M.D., 381 Myrtle Ave., Albany, N. Y., formerly with Division of Laboratories and Research, N. Y. State Dept. of Health
 Horace H. Selby, 3787 California St., San Diego, Calif., Chief Chemist, Hage's Ltd.

Public Health Engineering Section

Joseph M. Sanchis, B.S., 207 S. Broadway, Los Angeles, Calif., Chemist, Dept. of

Sanitary Engineering, Bureau of Water Works and Supply
 Orra Shonyo, Blytheville, Ark., District Supervisor, Sanitation and Malaria Control

Industrial Hygiene Section

Jorge L. Collada, C.E., Colima 60, Mexico, D.F., Mex., Civil Engineer, Industrial Hygiene Dept.

Food and Nutrition Section

Robert N. Berry, B.A., 55 S. Second West, Logan, Utah, Bacteriologist and Chemist, Morning Milk Co.

M. F. Brobst, B.S., 757 Revere Rd., Glen Ellyn, Ill., Charge of Nutrition and Vitamin Studies, Health Products Corp.

Edward M. Chace, 148 S. Mission Rd., Los Angeles, Calif., Chemist, U. S. Dept. of Agriculture.

Mrs. Eva B. Cronk, 1339 Vista St., Hollywood, Calif., Lecturer on Home Economics

James R. Esty, Ph.D., 322 Battery St., San Francisco, Calif., Director, Western Branch Laboratories, National Canners Assn.

Sophia S. Halsted, B.S., Dept. of Health, Detroit, Mich., Director of Nutrition

Margaret C. Smith, Ph.D., Dept. of Nutrition, Univ. of Arizona, Tucson, Ariz., Nutrition Chemist

Child Hygiene Section

Lenore H. Gageby, M.D., 4517 Lomita St., Los Angeles, Calif., School Physician, City Schools

Helen B. Pryor, M.D., 626 Tennyson Ave., Palo Alto, Calif. (Assoc.)

Public Health Education Section

Maurice LeBosquet, Jr., 231 S. LaSalle St., Chicago, Ill., Sanitary Engineer, Byllesby Engineering and Management Corp.

Paul Neiman, 826-33 Ave., San Francisco, Calif., General Secretary, San Francisco Tuberculosis Assn.

Reginald H. Smart, M.D., County Health Dept., Los Angeles, Calif., Consultant Physician, Tuberculosis Division

Louise E. Taber, M.D., 1944 Webster St., San Francisco, Calif., Division of Child Welfare, Dept. of Public Health

Helen L. H. Woodroffe, M.D., 844 Seventh St., Santa Monica, Calif., School Physician, City Schools

Public Health Nursing Section

Mrs. Guy W. Atwood, R.N., Route 6, Chattanooga, Tenn., County Nurse

Margaret L. Boyle, R.N., Health Dept., Worcester, Mass., Supervisor of Nurses

Lucinda Gonawein, 1016 Rawson Place, Fremont, O., School Nurse

Florence C. Johnson, R.N., 133 E. Haley St., Santa Barbara, Calif., Director of Nursing, Santa Barbara Visiting Nurse Assn.

Rachel K. Miller, R.N., 906 Blair Ave., Oakland, Calif., formerly Supervisor of Public Health Nursing, City Health Dept.

Mellie F. Palmer, R.N., 629 Third St., Des Moines, Ia., School Nurse

Phoebe E. Sheppard, Eagle Butte, S. D., Indian Field Service

Unaffiliated

Imogene H. Abbey, 328 N. Balcom Ave., Fullerton, Calif., Public Health Nurse, Orange County Health Dept.

Chesley Bush, M.D., Livermore, Calif., Medical Superintendent, Arroyo Sanatorium

Mabel G. Flanley, M.S., 4417 White Bldg., Seattle, Wash., Secretary-Manager, Washington State Dairy Council

Minerva B. Pontius, M.D., 123 S. East 1st St., Evansville, Ind., formerly Assistant Physician, State Hospital for the Insane

NEWS FROM THE FIELD

NEW MEXICO ASSOCIATION ELECTS OFFICERS

AT the meeting held in Los Vegas, N. Mex., July 17-18, new officers of the New Mexico Public Health Association were elected as follows:

President, Eugene P. Simms, M.D.

Vice-President, W. E. Kaser, M.D.

Secretary-Treasurer, Eleanor L. Kennedy, R.N.

The next annual meeting will be held in Santa Fe, April 30, May 1, 1935.

ITALIAN DECREE PROVIDING FOR THE PROTECTION OF WORKING MOTHERS

General Provisions—The decree of March 22, 1934, providing for the protection of working mothers in Italy coördinates and amends the previous legislation on this subject. The number of women affected is much larger than heretofore, because the decree applies to workers in practically all occupations—all workers except domestic servants; wives and other near relatives of employers; home workers under certain conditions; employees of the National Government, the provinces, the communes, and public benevolent institutions; public school teachers, if provision for their protection is not made otherwise; and agricultural workers. However, the provisions of the decree may be extended to women engaged in heavy agricultural labor if this is recommended by the Minister of Corporations.

Facilities for Nursing Mothers—An employer must permit every nursing mother to have two daily periods of 1 hour each in which to nurse her child, exclusive of the regular rest periods provided by law. The owner of every

establishment employing 50 or more women between the ages of 15 and 50 must provide a special room for nursing, unless there is in the neighborhood an infant welfare station where the mother may nurse her child conveniently. The nursing room must be well lighted, ventilated, and heated during the cold season; it must be kept clean and must be supplied with drinking water. If such a nursing room is provided in the establishment the nursing periods may be reduced to ½ hour each.

In establishments employing 100 women or more between 15 and 50 years old, factory inspection authorities may require the employment of a trained staff to care for the children of women employees while the mothers are at work.

Compulsory Insurance, Benefits and Premiums—Every woman between 15 and 50 years of age engaged in any of the occupations to which this decree applies is obliged to take out maternity insurance unless her wages are more than 800 lire a month. The maternity insurance is administered by the National Maternity Fund. The insured woman receives 300 lire in case of childbirth (twice the amount paid under the old law) and 100 lire in case of spontaneous or therapeutic abortion if it takes place after 3 months of pregnancy. The daily payment of half a lire to expectant mothers unable to work has been discontinued. A woman loses her right to the maternity benefit if she has been sentenced for infanticide or self-induced abortion, or in case of spontaneous or therapeutic abortion if she fails to present her claim within 30

days. A woman who enters other employment while she is on leave because of pregnancy and childbirth loses a part of her benefit.

Every woman carrying maternity insurance must pay 3 lire annually, to which the employer must add 4 lire. Any agreement to the contrary between employer and worker is prohibited by the decree.

The Government subsidizes the National Maternity Fund to the extent of 18 lire for each childbirth or abortion.

Penalties are provided for violations of this decree, which will become effective upon publication of the regulations for its administration.—*Gazzetta Ufficiale del Regno d'Italia*, Rome, No. 99 (Straordinario), 1934; texts of previous legislation.

NEW YORK SEWAGE WORKS ASSOCIATION MEETS

THE Fall Meeting of the New York State Sewage Works Association will be held at Oneonta, N. Y., October 5 and 6.

ALABAMA HEALTH UNIT REOPENS

ACTIVITIES in the Coffee County Health Unit have been resumed, with the appointment of Dr. William A. Stanley, of Union Springs, Ala., member A.P.H.A., as Health Officer. The unit was discontinued Jan. 1, 1933, because of lack of county funds.

JESSEN PRIZE TO DR. BURKHART

THE International Dental Federation, at its meeting at Lake Como, Italy, August 1-4, 1934, elected the following associate members of The Commission of Oral Hygiene:

Miss Neveu, Paris; Mr. Fabres, Nice; Mr. Seniot, London; and Mr. Krikos, Athens.

The Jessen Prize was awarded to Dr. Harvey J. Burkhardt, of Rochester, N. Y., member A.P.H.A., to be presented at the 1935 meeting in Brussels.

DELTA OMEGA OFFICERS

AT the annual meeting of Delta Omega, the honorary public health society, held at the Hotel Maryland in Pasadena, September 6, 1934, there was an attendance of 39 from the six chapters and one honorary member, Dr. M. P. Ravenel. New officers elected were Professor Charles G. Hyde of California, President; Dr. Huntington Williams of Baltimore, Vice-President; and Dr. W. G. Smillie of Harvard, Secretary-Treasurer. The retiring President is Professor Ira V. Hiscock of Yale. It was voted to establish a new chapter at Columbia University. The present chapters are located in order of establishment at Johns Hopkins, Harvard, Massachusetts Institute of Technology, Michigan, Yale, and California. The membership of the Society is 515, including 9 honorary members.

MISSOURI WATER AND SEWERAGE CONFERENCE

THE Tenth Annual Missouri Water and Sewerage Conference will be held at Carthage, Mo., October 15 and 16.

DEATH

DEATH OF DR. HOLLINGWORTH

DR. Walter G. Hollingworth, of the Bureau of Health of Utica, N. Y., died September 2. He was a member of the Food and Nutrition Section of the A.P.H.A. from 1919, and became a Fellow in 1926.

PERSONALS

BERNARD S. COLEMAN, F.A.P.H.A., of Passaic, N. J., has been appointed Secretary of the Tuberculosis Division of the New York Tuberculosis and Health Association. Mr. Coleman was formerly deputy relief director of the New Jersey Emergency Relief Administration.

DR. WALTER L. BIERRING, of Des Moines, Ia., member A.P.H.A., was the guest of honor at a dinner September 4, at Los Angeles, Calif., sponsored by the Los Angeles County Medical Association.

CONFERENCES

- Oct. 5-6, Fall Meeting, New York State Sewage Works Association, Oneonta, N. Y.
- Oct. 8-10, Annual Meeting of the Association of Military Surgeons of the United States, Medical Field Service School, Carlisle Barracks, Pa.
- Oct. 15-16, Tenth Annual Missouri Water and Sewerage Conference, Carthage, Mo.
- Oct. 15-18, 17th Annual Meeting of the American Dietetic Association, Washington, D. C.
- Oct. 15-19, American College of Surgeons, Boston, Mass.
- Oct. 15-19, Annual Convention, New York State Nurses Association and its affiliated bodies, Buffalo, N. Y.
- Nov. 2, Mid-Year Meeting of the New York State Association of Public Health Laboratories, at the State Laboratory, Albany, N. Y.
- Nov. 13-16, Southern Medical Association, San Antonio, Tex.
- Nov. 16, 17, 60th Anniversary Meeting, New Jersey Health and Sanitary Association, Berkeley-Carteret Hotel, Asbury Park, N. J.
- Dec. 27-30, Annual Science Exhibition of the American Association for the Advancement of Science and Associated Societies, Pittsburgh, Pa.
- April 29-May 3, 1935, 19th Annual Clinical Session of the American College of Physicians, Philadelphia, Pa.

JOURNAL OF HOME ECONOMICS

official magazine of the

AMERICAN HOME ECONOMICS
ASSOCIATION

An authoritative up-to-date interpretation of progressive home economics is now more than ever necessary. It is an essential for the home economist; it is necessary as a guide for all who are active in fields of work related to home economics; it is necessary as an interpreter for all who wish to co-operate in explaining to the public the special service and value of home economics in a modern world.

The Journal of Home Economics fills these needs.

Public Health in Tudor England*

SANFORD V. LARKEY, M.D.

*Assistant Professor of History of Medicine, University of California,
Huntington Library International Research Fellow*

IN studying the development of public health activities in 16th century England, we find that it runs parallel with and, in fact, is contingent upon the growth of a strong, centralized government under the Tudors. The attitude of the State, especially in the reign of that amazing ruler, Elizabeth, was an enlightened one, seeking to guard and foster the welfare of all of the people. We are apt to forget today that in Elizabeth's time government regulation of industry and of many phases of the life of the people was the accepted order. It is significant that from such a philosophy of government sprang many of our basic public health procedures.

Manifestations of this ideal are seen in the various efforts to better the sanitary and health conditions of the people, not only in attempting to control epidemics, but in aiming also to eradicate some of the fundamental factors in the cause and spread of disease. Housing plans were proposed to relieve the overcrowding of cities, pure food laws were passed, rules made to keep the streets

clean, and a commission appointed to regulate the disposal of sewage. All of these projects had the definite purpose of protecting and improving the health of the populace.

A Commission on Sewers had been established as early as the 15th century by Henry VI. It provided severe penalties for the pollution of streams, and these were enforced. Tanners and brewers were required to drain their waste into cesspools. Owners of swine had to provide suitable accommodations for their animals, and to take special precautions that there should be no drainage from the sties into neighboring streams. In connection with animals it is interesting to see that Henry VII recognized the menace to health from slaughterhouses and passed a law forbidding them within cities or towns, "lest it might engendre sicknes, unto the destruction of the people."

For many years there had been a statute that any one throwing dung or offal into the streets would be fined 40 shillings, a considerable sum in those days, and there is abundant evidence that this was enforced. At first the task of sweeping the streets was left to the householder, but later it became a municipal function and men were hired

* Read at a Joint Session of the Child Hygiene and Public Health Education Sections of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

by the towns and cities for the purpose. The unsanitary conditions of streets was considered an important factor in plague epidemics, and rules for cleaning streets are embodied in the Plague Orders.

It was realized that pure and wholesome food was essential to health. As Elizabeth stated in a proclamation: "We must provide . . . foode, and other like necessities for mans life upon reasonable prices, without which no citie can long continue," and, as another proclamation says, "food should be good, sweete, sound, and wholesome for mans body." The standards and quality of food products were regulated by various laws, such as the *Assize of Bread*. The government proceeded strenuously against anyone selling bad or tainted food, and in one case the punishment certainly fitted the crime: any dealer who sold bad pork was to be put in the pillory in the market place and the rancid flesh burned in his face. The problem of adequate food supply in times of dearth was a serious one, and in 1577 John Dee, Queen Elizabeth's physician, suggested that the government establish stores of grain to meet such emergencies. This was done in a small way by various municipalities, and in 1623 James I carried it out on a large scale. One of the reasons he gives for his action will strike a sympathetic note today. He says: "The Kings most Excellent Majestie, observing that in times of dearth His loving Subjects (especially the poorer sort) are pinched with the great want and deere prices of Corne, and that the Treasure of the Kingdome, in those times is much exhausted, in providing Corne from foraine parts, and againe, that in times of plenty, the Farmour and Husbandman, by the low prices, and want of vent of their Corne, are hardly able to support their necessary charge nor the Landlord to uphold his rent." He hopes to stabilize prices by gathering stores in various parts of the kingdom, where, in

times of famine, corn will be sold at a fixed fair price.

The rapidly increasing population of London was a cause of great concern to the government, as it realized the dangers from disease in such a congested area. As Elizabeth herself put it, in a proclamation of 1580 against tenements: "Yet where there are such great multitudes of people brought to inhabitate in small roomes, whereof a great part are seene very poore, Yea, such as must live of begging, or by worse meanes, and they heaped up together, and in a sort smothered with many families of children and servantes in one house or small tenement, it must needes followe (if any plague or popular sicknes shoulde by Gods permission, enter amongst those multitudes) that the same would not only spread it selfe and invade the whole city and confines, as great mortalitie should ensue to the same." The aim of this law was to prohibit any new buildings within the city area, or the subdivision of existing houses into tenements.

Elizabeth's Stuart successors attempted to further these plans, but they met with vigorous opposition from selfish private interests, who put their own gain before the health of the community. Both James I and Charles I had very extensive schemes for city planning, regulating all phases of building. Among the proposals of Charles was this—"The windowes of every whole story to be of more height than breadth to the end the Roomes may receive ayre for health." In light of the recent survey of the present living conditions of the London poor, emphasizing the fact that large numbers still inhabit ill-lighted and unsanitary basement rooms, it is amazing to find that this law of Charles I prohibited cellars being used as lodgings. It is a sad commentary upon civilization that such far seeing plans were discarded under the *laissez faire* system.

However, the general efforts of Elizabeth did much to improve conditions, probably more effectively in the towns than in London itself, and I think it should be emphasized that the sanitary conditions of 16th century England were much better than we usually have been led to believe. J. H. Thomas, in an important recent work, "*Town Government in the Sixteenth Century*," has made a study of all phases of sanitation of some 12 English towns, and he says, "If a wider knowledge of town life as revealed by town *Records* refutes the view that towns remained filthy and entirely neglected by ignorant and irresponsible authorities, so must a fuller acquaintance with the little that is known about the origin of the diseases of the 16th century modify the opinion that town conditions caused those diseases." He compared the state of these towns in the 16th century with that in the middle of the 19th century, as revealed in the Royal Commission Survey of 1844-1845, and comes to the conclusion that in almost every respect the towns were cleaner and more healthy in the 16th century than they were in the 19th century. He says, "If some period in town life must be labelled as a time of in-sanitation, then the 19th century should be chosen."

One of the most important public health activities of the government was the control of epidemics. From the early part of the century the medical profession played a prominent part in this endeavor, through the College of Physicians. This had been founded in 1518 by Henry VIII on the advice of his physician, Thomas Linacre, and it is significant that from that very year date some of the most important public health measures, put into effect by the Privy Council, such as the isolation and marking of houses infected with plague, the isolation of clothes and goods of those dying of the plague, the first London Plague Orders, and the first

time Bills of Mortality are mentioned.

Considerable powers in matters of health were delegated to the College of Physicians, and also to the Barber-Surgeons Company, founded in 1540. Thus the College of Physicians had charge of the licensing of doctors in London and sought to curb the quacks and charlatans who preyed on the public. Since there was no such authority outside of London, a prominent physician, John Securis, suggested a strict licensing law for all physicians, surgeons, and apothecaries, on the basis of educational qualifications. On the advice of the College of Physicians, the apothecaries were taken out of the Grocers Company and set up as a separate company. From the appearance of most modern drug stores they seem to have gone back again. The apothecaries were required to adhere to the official *Pharmacopoeia* drawn up by the College. The proclamation ordering this move says it was done "out of Our Royall care for the health and preservation of our Subjects."

For control of the plague there were two sets of *Orders*, those for London and those for the country at large. In general, the provisions of these were much the same, although the organization differed. In London the Lord Mayor and the Aldermen were in charge, while in rural communities the Justices of Peace of a county, except those from infected areas, were to meet together, prescribe rules for the isolation of infected towns, and to put into effect the orders outlined by the government. The next provision in both of these *Orders* was a very necessary one, the raising of funds by taxation to meet the costs of the campaign. The government accepted the responsibility of relief in such a crisis. The money thus raised was to be used not only in general measures, but as the *Orders* themselves say "for the finding of victuall, or fire, or medicines for the poorer sort, during

the time of their restraint." Men were to be hired to examine all suspected patients in order to isolate all those infected and to obtain an estimate of the extent of the epidemic. The ministers, curates, and church wardens were to certify in writing the number of infected, and also of those dying within their parishes, with the probable cause of death. These findings were elaborated into the weekly and yearly Bills of Mortality. As such Bills apparently were used first in England, they mark the beginning of vital statistics.

Every house that contained one stricken with this dread disease was to be marked with a cross and the words "Lord have mercy upon us." Attempts were made to localize the epidemic and any infected person going abroad was treated as a felon. There were efforts made throughout the country to segregate plague patients in isolation hospitals. Sometimes these were rather makeshift dwellings outside the towns, but in 1592 a pesthouse was established in London.

Assemblies of people such as plays, bear-baitings, and fairs were forbidden. Sometimes the schools were closed. Preparations were made for the burial of the dead in a place apart. The clothes, bedding, and other goods of those dying or recovering from plague were usually burned, and the owner recompensed from the general funds.

At the end of the general *Orders* is a collection of remedies, "by the best learned in Physicke within this Realme . . . without charge to the meaner sort of people." The wealthy could afford to pay the doctor who cared for them during the plague, but poor people could not and the government provided such service. In 1583, in a translation of Ewich's *Of the Ductic of a Faithfull and Wise Magistrate*, it was suggested that the commonwealth hire physicians, surgeons, and apothecaries to deal with

plague patients. While this had been done sporadically, finally the College of Physicians put it into permanent practice, thus bringing into being the first Public Health Physician. These men were bound by oath to remain at their posts, and many died of plague. That their services were appreciated is shown by the provision for pensions to the widows of such doctors.

It would seem that everything humanly possible was done to combat the disease, along the lines of control measures. In spite of these efforts the plague continued its ravages, and in the more severe epidemics, as in 1603 and 1625, in each of which over one-sixth of the population died, the public became panic-stricken, and the system broke down. The rules could not be enforced, the dead were left unburied, and each one looked out for himself.

An element in increasing this state of panic was the teaching of certain religious fanatics that the plague was a sign of the wrath of God, that it was not infectious, and that to attempt to avoid it was an indication of a lack of faith in God. The government took a firm stand in this matter, and in the *Orders* there is a section forbidding persons "to utter such dangerous opinions upon payne of imprisonment." A number of preachers were thrown into jail for continuing to spread such doctrines.

The important lesson that may be learned from this experience of the past is the part that human frailty plays in the struggle against disease. Ignorance and fear can upset the most logical plan, and we have seen that when government became weak and lost its control, all the admirable efforts in housing and pure food regulations were sacrificed to selfish greed. Education can do much to overcome ignorance but also there must be courageous and strong leadership and a determined social-consciousness of the public.

Responsibilities of Health Authorities to Prevent the Spread of Syphilis*

J. ROSSLYN EARP, M.R.C.S.,¹ DR. P.H., F.A.P.H.A.

Director, Bureau of Public Health, Department of Public Welfare, Santa Fe, N. M.

IT is our responsibility to stop the spread of syphilis wherever a barrier can be erected in its path. The logical position for the first barrier is in the field of prophylaxis. At the beginning of the present century Metchnikoff and Roux discovered and demonstrated beyond the possibility of doubt that the spirochete of syphilis may be killed upon the surface of the mucous membrane. Successful application of this discovery was made during the world war by the British Army which distributed prophylactic packets for self-disinfection and by the American Army which established centers for skilled disinfection. But neither of these systems has achieved any large measure of success in a civilian population. An English Committee of Enquiry on Venereal Diseases set up in 1923 reported: (1) that skillfully applied disinfection after intercourse would often prevent infection, (2) the success of any general public facilities for self disinfection is likely to be small, (3) that they could find no reason why people should not be allowed to purchase disinfectants for their own use and, therefore, (4) that the English

law should be altered "so as to permit properly qualified chemists to sell *ad hoc* disinfectants, provided that such disinfectants are sold in a form and with instructions for use approved by some competent authority."

During the last ten years no competent authority has been found willing to sponsor a set of instructions. Dr. Taliaferro Clark¹ reported for this country in 1931 that "in the states and cities in which prophylactic stations have been established they have been so poorly patronized that they have been given up." It still remains true that an ointment containing 33 per cent of calomel will, if thoroughly applied to the exposed surface within a few hours of exposure, prevent syphilitic infection. It should be applied if possible within 1 hour and in any case within 8 hours. I confess that the only use that I have made of this knowledge has been to urge upon certain of my audieces that if ever they find themselves in a position where they may have been exposed to infection they shall without delay, be it day or night, apply to a physician for prophylactic treatment. I hope that some of them have done so and that the physicians have received them cordially. My hope, however, is not very stout.

Treatment of contagious syphilis with arsphenamine or even with bismuth

* Read at a Joint Session of the American Social Hygiene Association and the Public Health Nursing Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

rapidly renders it non-contagious. This fact provides us with our second barrier: indeed, with our Hindenburg Line. For if we fail at this barrier we shall lose the war.

The provision of free treatment in accessible and attractive clinics has been the main element in the British campaign against venereal disease since the war. Colonel Harrison² offers statistical evidence that there has been a slight decrease of syphilis in England and Wales. That the English scheme has failed to "eradicate" syphilis Colonel Harrison freely admits, and it will be profitable for us to examine the four main causes which, in his opinion, explain the failure: "(1) The inability of many of the infected to remain continent until pronounced cured. (2) The large numbers of persons who cease attendance too soon. (3) The imperfection of treatment centers. (4) The ignorance of many persons in the community that they are infected."

We need not perhaps take the first cause too seriously. Fortunately it is not necessary for the patient to remain continent during a 2 year course of treatment. It is possible for him or her to remain continent until no longer contagious. The second and third causes are removable, not without effort, and the fourth cause leads directly to another responsibility of health authorities which we must consider.

Before doing so let us note that in the rural districts and smaller towns of the United States treatment centers are not at all likely to succeed while the bulk of the organized medical profession is opposed to them. In England the situation is entirely changed by the operation of the National Health Insurance Act. Similar legislation would change the situation here, but until we have health insurance we must rely on the private treatment of a majority of our cases. This is a further handicap because it means that we have to per-

suade every practising physician to persuade each of his patients that inadequate treatment is more dangerous than no treatment at all. We must also exert ourselves that the practising physician be supplied with free drugs and at least a minimum fee from the public treasury; for he can hardly be expected to be enthusiastic in prolonging treatment when he has to bear all the expense thereof himself.

I have said that the ignorance of many people of the fact that they are infected leads us to another responsibility. We are responsible for making the discovery. We must find our cases of syphilis and find them early. We face no responsibility more urgent than this.

First we have the Wassermann test and the various other serological tests for syphilis. "The Utopian day has not yet come," says Dr. Moore³ "when every patient who consults a physician, for whatever cause, can have made a routine diagnostic blood Wassermann test. There are two types of patients, however, in whom the test should be made an absolute routine: (1) any patient in whom, for any reason, a general medical examination is made; (2) every pregnant woman."

Our recent survey experience in New Mexico has brought fresh evidence of the case finding possibilities of the routine Wassermann. A survey of a random sample of the population shows that we have some 21,000 cases of syphilis among the adults of the state. A census of all cases under treatment in the state on a given day shows 1,011 under medical care. The routine application of the Wassermann test can thus declare to us in our state about 20 times the number of cases that are actually known to us. When we consider further that almost 8 per cent of our adult population give positive reactions to the test (the percentage is higher in the cities, lower in the rural districts)

it must be obvious that it would be profitable to the doctors to avail themselves freely of this test. It is true that from the public health viewpoint many cases so discovered have passed the contagious stage.

In applying the test to pregnant women we are, on the other hand, sure that most positive cases will be both contagious and in the act of passing on the contagion. The study of 1,467 pregnancies in women with latent syphilis collected by the Coöperative Clinical Group shows that a syphilitic woman, untreated, has only 1 chance in 6 of bearing a live healthy infant, as compared with the normal woman's 3 chances in 4.⁴ We must therefore make the Wassermann test an integral part of every prenatal program.

I believe that the women's clubs should be made to share our responsibility in this respect. In addressing such organizations I have insisted that if their members, the most respectable members of the community, will insist on being given a Wassermann test each time that they become pregnant, then the obstetricians in that community will very soon make the test a matter of routine.

Other speakers will discuss in detail the methods of case finding. I am glad because I feel that this subject forms a fitting climax to this symposium. Let me say that I consider that Smith and Brumfield⁵ have completely proved their case that "it is practical to trace sources of infection and exposures in syphilis." On only two occasions did they find patients unwilling to name their consorts. The young people of this generation are ready to tell us. I am doubtful whether the doctors are equally ready to ask, although I agree with Dr. Smith that if the private physician will accept this responsibility nobody is better equipped to carry it through. H. W. Cummings⁶ has suggested that health authorities should

provide social workers to work with private practitioners as well as clinics in case finding. I would rather provide public health nurses who are, I believe, in a more strategic position than social workers.

I do not expect you to disagree with anything I have said up to this point. Now, however, I broach a questionable responsibility about which there is bound to be difference of opinion. People are always ready to quarrel on a subject about which they feel deeply, and people are always liable to feel more deeply, on a subject the less they know about it.

I approach the subject of sexual mores. To what extent is the incidence of syphilis determined by different kinds of sex behavior? To what extent, and by what methods can sex behavior be modified?

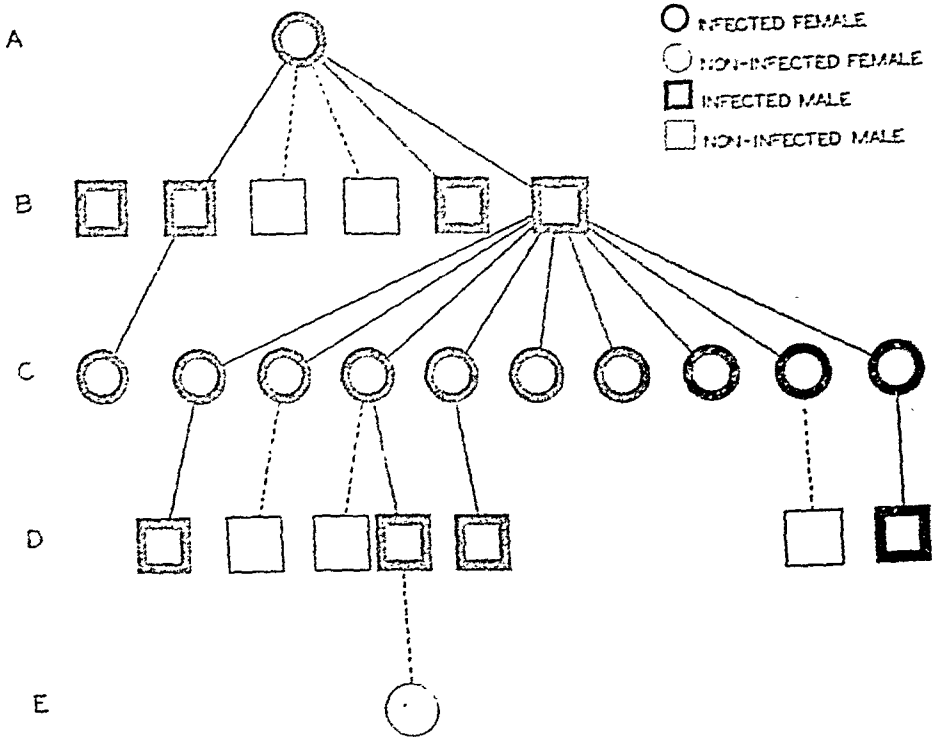

If you will look at the chart reproduced from the *Journal of Social Hygiene* for January, 1933, you will perceive that two individuals are especially responsible for the spread of syphilis in this little epidemic. The first is a prostitute, the second is a man of promiscuous sexual habits. This chart represents as good evidence as you will find that these two types of sex behavior tend toward the spread of syphilis.

Assuming for the moment that it is our responsibility to offer combat to prostitution and to promiscuity, there are two weapons offered to our hands: law and education. Let us examine the possibilities of each of these weapons in relation to each of these presumably undesirable social customs.

Historically the first method tried on the prostitute after the introduction of syphilis into Europe was abolition. An order of the town council of Aberdeen, Scotland, quoted by Taliaferro Clark¹ reads:

For the protection from a disease which came out of France and strange parts, all light women desist from their vice and sin of

HOW SYPHILIS SPREADS

A physician in a middlewestern city asked the State Health Department to trace the source of infection in 4 cases of fresh syphilis in his practice, all men (B). An investigation resulted which revealed 19 infections among 25 persons examined. Three of the original 4 men patients were infected by one woman, a prostitute (A). These men in turn infected 10 other women, 6 of whom were young girls (C). Four girls infected 4 other men (D). The fourth man (B) was traced to a different source.

DATA FURNISHED BY THE MINNESOTA DEPARTMENT OF HEALTH

Chart by A.S.H.A., New York

venery and work for their support on pain less of being branded with a hot iron on their cheek and banished from the town.

Nevertheless the light women did not desist from their vice and sin of venery.

Next an attempt was made to regulate the same vice with the object of isolating prostitutes from the general population and removing from the traffic those who were infected. Commonly but not universally it is agreed that "regulation" is a failure. In a recent review of the subject, Colonel Harrison⁷ maintains that in certain

circumstances regulation of prostitution can be effectual. Regulation proved successful under his direction when he abandoned all attempts to isolate infected women, assumed all prostitutes to be infected, and concentrated on measures designed to prevent the spread of contagion.

However, whether or not it is successful, regulation will always be opposed in countries with an Anglo Saxon tradition by those who reflect—

How oft the sight of means to do ill deeds
Makes ill deeds done.

The same Anglo Saxon tradition lends power to those modern health officers who have reverted to the method of the Aberdeen fathers. Of course police methods have been improved since the days of branding cheeks. One of our fellow authorities kept, and for all I know still keeps, a group of under-cover agents⁸ who live by double-crossing their friends in the trade. Under this system both prostitutes and police may well feel uneasy, and it is not difficult to accept the claim that "the whole procedure has worked a very severe hardship on the prostitution underworld." What one would like to know is whether this and similar repressive measures have decreased the incidence of syphilis. Being unable to answer this question I turned for help to the American Social Hygiene Association, and Mr. Johnson came very kindly to my rescue. He sent me a reprint of an article published some years ago⁹ in which he had marked the following paragraph:

Municipal policy toward prostitution has tended toward regulation and certain conditions have prevailed which are generally believed to have venereal diseases as an accompaniment. No statistical evidence has ever been available to show whether there was more or less infection under such a policy and under such conditions.

Mr. Johnson comments that "this situation still exists." What we did not know in 1927 we still do not know in 1934. Our first responsibility is perhaps to find out what effect legal repression of prostitution has on the incidence of syphilis and then to act in the light of our knowledge.

Before taking any action of this kind, however, do let us consider what effect it is going to have on our attempts to trace the transmission of syphilis from case to case.

Laws are also available for the punishment of those guilty of promiscuous sexual relations. More than that,

laws have been seriously recommended which provide a 6 months jail sentence for any extra-marital sexual relations whatever. The enforcement of such laws would certainly stamp out venereal disease. But does anyone imagine that they could be enforced? Col. P. M. Ashburn¹⁰ reported in 1927 that 54 per cent of 550 West Point students, ages 21 to 27 years, had had sex intercourse on an average of 23 times.

And again, if we make ourselves responsible for the enforcement of such laws, shall we be able to trace from case to case the transmission of syphilis. "Young man" we shall say, "if you will give me the names of all the girls with whom you have had any sex relations I shall, of course, have to see that they are sent to prison for 6 months, but I shall also see that the disease is thoroughly treated."

And once more, what do we really know of the influence of sex behavior on the incidence of syphilis?

Two years ago I had to address a group of sociologists. The above subject appeared to me one on which we might find common ground. In seeking material on which to base a discussion of this subject I was astonished as well as disappointed with the absence from sociological literature of any exact observations on the relationship between social behavior and the spread of the venereal diseases. I should have thought that sociologists would have been doubly interested in making such observations. In the first place a relationship having been established, objective records of pathology might be used as a clue to the sex-social organization of a given society. In the second place, the contribution of venereal disease to family disorganization and racial decay must surely be a matter of importance to sociologists. I take as an example the work of Rivers¹¹ among the Todas of British India. He writes:

There seems to be no doubt that there is little restriction of any kind on sexual intercourse . . . instead of adultery being regarded as immoral, I rather suspected, though I could not satisfy myself on the point, that according to the Toda idea, immorality attaches rather to the man who grudges his wife to another. . . .

So far as I could tell, the laxity in sexual matters is equally great before and after marriage.

Here then we find in practice the kind of sexual behavior at present advocated by Dora and Bertrand Russell. Would it not be of exceptional interest to know something about the incidence of venereal disease in such a community? But not a single observation bearing on this subject can I find.

With other similar studies I had practically the same experience. Malinowski¹² in a two volume report on the Trobriand islanders mentions incidentally one epidemic of acute gonorrhea which was useful to his study, but gives no other clue as to the incidence of venereal disease among these peoples to whom adolescent promiscuity appears as normal and proper recreation.

My paper grows too long and I have as yet said nothing about education as a method of controlling sex behavior. Those most familiar with my checkered past will know me as an ardent advocate of sex education. But more and more I wish to dissociate sex education from the campaign against syphilis. The object of sex education must be positive, constructive, never inhibitory. I do not want my students to feel that I am lecturing them into some accepted moral code. I want them to know that I am helping them to knowledge born of experience and experiment; that I expect them to fashion from it their own philosophy of life. The facts of venereal disease should be only a minor portion of this knowledge.

I do not deny that such education is likely to diminish the incidence of syphilis, but I do not know, and as a sex educator it is not my main concern. And I recognize, of course, that the facts about syphilis belong in the forefront of any campaign of popular health education.

SUMMARY

A knowledge of the possibilities of prophylaxis should be widespread and physicians should be prepared to give prophylactic treatment to those who ask for it.

Our main responsibility is to find cases early, to bring them under treatment, and to keep them under treatment until cured. The barrier of early and complete treatment is essential to the control of syphilis, and careful epidemiology is essential to the erection of this barrier.

Research is urgently needed on the relationship of sex-social behavior to the incidence of syphilis. Accurate morbidity statistics will greatly aid such research.

Epidemiological Value of Isolating Bacteriophage in Outbreaks of Intestinal Infection *

ROY F. FEEMSTER, M.D., DR.P.H.

Massachusetts Department of Public Health, Boston, Mass.

THE bacteriophage has been largely a laboratory curiosity and a subject for controversy and speculation. The principal attempt to make use of it in a practical way has been as a curative agent, upon which opinions differ. Other useful applications of the phenomenon no doubt await discovery when more information is accumulated. With the purpose of determining whether there might be any public health applications of the phenomenon, a study was begun in 1932, undertaken largely because of the success with which the isolation of bacteriophage was applied in an outbreak of bacillary dysentery in a large institution (Medfield), the main features of which are reported in a paper now in press.¹

In this epidemic it appeared that finding a bacteriophage in the stools from those affected which was active against the bacillus causing the disease was a useful means of aiding to differentiate these cases from those due to other causes. Stool cultures had proved unreliable for 2 reasons: (1) The bacillus was soon eliminated from the intestine, and when there was delay in obtaining specimens no organism was cultivated from them; (2) Specimens

had to be mailed to Boston for examination, and even stools obtained at the proper time were often negative. The epidemic had begun early in the summer in one ward. A Hiss-Y dysentery bacillus was recovered from one patient but not from others. Isolation and general sanitary measures caused an abrupt cessation of cases.

Six weeks later the infection appeared again, this time in most of the buildings of the institution. During the second outbreak over 90 stools from clinical cases were examined, and from only 6 was the dysentery bacillus obtained. At the same time 81 stools were examined for bacteriophage and 29 were found positive. The figures are more striking when divided into groups according to the week of the disease. During the first 7 days bacilli were found in 28 per cent of the specimens examined, while bacteriophage was found in 33 per cent; during the second week bacteriophage was found in 80 per cent and bacilli in 13 per cent; during the third week bacteriophage was found in 45 per cent of specimens and bacilli in none. Thereafter neither was found with any regularity. Stools of individuals not affected did not contain bacteriophage. The bacteriophages isolated in this outbreak were active against all members of the Flexner group, as well as the Sonne and Shiga bacilli.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

Meanwhile an urgent necessity for finding other means of gaining information as to the etiology of outbreaks of gastroenteritis was felt. Such outbreaks are perhaps the most frequent variety that the epidemiologist is called upon to investigate, and in many instances, due to the short duration of illness, he does not arrive until the peak has passed and a majority of the cases are in the convalescent stage. Under such circumstances determination of the etiological agent is difficult. Stool cultures are unsatisfactory because in most instances no suspicious organism is isolated. Even if one or two stools yield some organism which might be responsible, it is difficult to prove that the other cases have been caused by the same agent. Agglutination tests cannot be entirely depended upon, since some individuals may have agglutinins from previous attacks or sub-clinical exposures to the organism.

Since bacteriophage active against the invading organism has been demonstrated repeatedly in the stools of individuals suffering from illness due to various types of intestinal pathogens, it seemed that isolating bacteriophage from the stool might give some light as to the cause of an illness. Since the bacteriophage usually appears in the stool during the convalescent stage, the method would have the advantage of

providing evidence long after the expectation of isolating the bacterium had passed. It was decided, therefore, to filter stools from these epidemics and set them up against a number of intestinal pathogens.

The usefulness of the procedure would depend upon several factors: (1) the chances of picking up a bacteriophage which had no relation to the outbreak; (2) the specificity of those isolated; (3) the regularity with which bacteriophages are recoverable from those ill, in contrast to those not affected.

In order to check up on the first factor, samples were collected from many sources, filtered, and placed in contact with a group of the more common intestinal bacteria. The bacteriophages isolated from these sources are summarized in Table I. It will be seen that except in sewage samples they are relatively rare. The chances of a single individual picking up a bacteriophage might be of some significance, but the chances of several individuals simultaneously picking up the same one would be quite small. That such is the case is indicated by the failure to find them in a large number of stools examined from persons involved in various outbreaks which have been studied not due to the dysentery bacillus.

When we turn to the specificity of the

Total	437	41	12	14	78	56	74	55	25	41	12

* None of these stools were from dysentery outbreaks.

bacteriophages we find that they can be divided into several rough groups:

1. Those active against *B. typhosus* only
2. Those active against the Flexner dysentery group
3. Those active against all dysentery bacilli, including Shiga and Sonne
4. Those active against *B. typhosus*, *B. dysenteriae* (Shiga), *B. dysenteriae* (Sonne), and *B. enteritidis*
5. Those active against all of the group of intestinal pathogens used
6. Those active against *B. coli*

Not all can be placed in the above groups as there are considerable variations in valence. No doubt mixtures of bacteriophages were dealt with in some cases, particularly from sewage samples, but repeated platings of some of wide valence (Group 5) and isolations from plaques failed to narrow the valence. Perhaps more persistent efforts will reveal that some of them are mixtures.

Another fact which stood out conspicuously was that the colon bacillus was very seldom included in the valence of bacteriophages isolated with the intestinal pathogens. Frequently a colon bacteriophage was isolated from the same specimen that contained other phages, but it was usually quite specific for the colon bacillus, and the others did not often attack the colon bacillus. Most observers have remarked upon the regularity with which Shiga bacteriophages attack the colon bacillus, but this has not been true in the present study. The explanation is not yet apparent.

This irregular and wide valence adds uncertainty to the interpretation of isolations from stools until several are found and shown to be the same variety in different individuals in the same epidemic. In order to demonstrate that they are the same, it is necessary to determine their valence against a list of the commoner intestinal pathogens.

It has already been shown that bacteriophages are recoverable with great regularity from patients convalescing

from bacillary dysentery and are absent from stools of those not affected. Whether this is true of other intestinal infections awaits demonstration.

Meanwhile outbreaks of gastroenteritis were occurring and attempts to make use of the method were being tried. Most of the outbreaks were mild to moderately severe diarrheas occurring in short, sharp epidemics, in contrast to the more drawn out course of bacillary dysentery in an institution. Those affected were not prostrated and few or none showed blood or mucus in the stool (see Table II). Stool cultures yielded an occasional organism not easily classified and also an occasional bacteriophage active against some of the pathogens used in the search. The same bacteriophage could not be recovered from a sufficient number of individuals to be significant, nor were those isolated ever active against the organisms found in the outbreaks. Either the intestinal disturbance was due to organisms not included in the list used, or the attacks were so mild that bacteriophages did not appear in the stool. We must not lose sight of the fact that some strains of bacilli are not susceptible to lysis by bacteriophage, though it does not seem plausible that all of the occasional organisms isolated from stools in these outbreaks could have happened to be insusceptible to lysis.

During one season semi-monthly samples were collected from 3 popular beaches near Boston during the spring before the bathing began, and weekly samples during the summer months. The plan was to examine these for bacteriophages to discover the usual ones present with the expectation that a new one might appear if an intestinal outbreak should occur among those frequenting the beaches. One hundred families at each beach were visited regularly and 273 physicians in the communities where the beaches were located agreed to report any intestinal disorders

TABLE II

OUTBREAKS OF INTESTINAL INFECTION

Outbreak	Type	Population Involved	Cases	Causative Agent	Probable Mode of Spread	Character of Symptoms	Number of Specimens Examined	Isolation of Bacteriophage Useful
Medfield	Institutional	2,100	100	<i>B. dys.</i> (Miss-Y)	Contact and carriers	Violent diarrhea, fever mucus, blood	81	Yes

Waverly	Institutional	2,000	156	<i>B. dys.</i>	Contact and food	Severe diarrhea, mucus and blood	47	Yes

which occurred. It happened that there was no outbreak among the groups studied during the season. Not even a single case of severe diarrhea was reported. The only information obtained, therefore, was the normal bacteriophage content of the waters of the beaches.

An outbreak in a family in Worcester,

tailed figures are not yet available. The percentages given include examinations of samples from all cases of diarrhea occurring during the outbreaks, some of which were certainly not due to the dysentery bacillus. In isolating bacteriophages in these 2 outbreaks 2 markedly susceptible strains

TABLE III
DYSENTERY BACILLI AND BACTERIOPHAGES ISOLATED FROM STOOLS
DANVERS OUTBREAK

Week after onset	Dysentery Bacilli			Bacteriophages		
	Specimens examined	Number positive	Per cent positive	Specimens examined	Number positive	Per cent positive

2	28	6	21.4	6	4	66.7
3	28	2	6.7	4	2	50.0
4	24	3	12.5	14	8	57.3
5	29	1	3.3	8	4	50.0
over 5	39	0	0	11	5	45.4
	195	30	13.4	58	32	55.2

however, presented the same situation as in the institutional outbreak mentioned above. Three children were sent to a hospital with a very severe diarrhea. A dysentery bacillus was isolated from the most recent case. Bacteriophages were recovered from the stools of the other 2 children, and at a later date one was found in the stool of the child from whom the organism was isolated. Stools from 2 other children who had had mild attacks were examined and a bacteriophage was found in one. Here again isolation of bacteriophage aided in proving conclusively that all the children were suffering from the same illness.

During this summer outbreaks of bacillary dysentery occurred in 2 other institutions. In an outbreak in Danvers 13.4 per cent of the specimens examined for bacilli yielded a Hiss-Y dysentery bacillus and 55.2 per cent of the specimens examined for bacteriophage were positive. The percentage by weeks is shown in Table III. In an outbreak in Waverly bacilli were found in 10.7 per cent of the samples examined and bacteriophages in 49 per cent. This last outbreak occurred so late that more de-

were used as well as a strain isolated from each institution. Several bacteriophages were obtained which would have been missed if the 2 stock strains had not been used. All of the bacteriophages were shown to be active against the organisms isolated from the institutions. Some of the dysentery bacilli isolated were found to be insusceptible to lysis by the bacteriophages at hand.

DISCUSSION

It was a considerable source of disappointment that isolation of bacteriophages failed to be of aid in studying the more elusive epidemics of intestinal infection usually encountered. The fact that the method can be applied to bacillary dysentery, while interesting and of value in certain instances, is not so useful since the usual methods of studying such outbreaks are more satisfactory. However, it is not unlikely that by increasing the list of organisms used in testing, or by some other variation, the method may yet be made to yield information in such intestinal disturbances.

In making isolations from dysentery cases it is recommended that one or two

markedly susceptible strains of bacilli be used until it is ascertained that an organism recovered from a case in the outbreak will pick up bacteriophages from all stools in which they are present.

METHODS USED

Except for the time consuming operation of filtering through a Berkefeld filter, isolation of bacteriophages is no more complicated than isolating bacteria. Some of the ways of simplifying filtration were reported in a recent paper.²

COLLECTION OF SPECIMENS

The specimens should be collected without any differential or inhibiting fluid such as used in typhoid and other culture outfits. A satisfactory method is to saturate thoroughly and cover the cotton swabs in a diphtheria culture outfit. Drying does not appear to inactivate the bacteriophage at this stage.

ISOLATION INVOLVING FILTRATION

The simplest method of isolation is to place 5 to 10 c.c. of plain broth in contact with not more than 1 gm. of feces and after 15 to 30 minutes decant into a Berkefeld filter and pass through an "N" candle. To a tube of broth, seeded lightly with the organism causing the outbreak or with a stock strain, add 0.5 c.c. of the filtrate from the stool and incubate 18 to 24 hours. A control tube containing only the organism should be set up. If a strong bacteriophage is present, the tube containing the filtrate may be clear while the control will be turbid. If the bacteriophage is weak, no clearing may appear, in which case it is necessary to make sure no bacteriophage is present. There are 3 methods by which this may be done.

1. The most accurate method of checking up on doubtful tubes is to transfer 0.05 c.c. to an 18 hour broth culture of the organism, thoroughly mix,

and then smear 0.1 c.c. evenly over the surface of an agar plate. This is best done with a bent glass rod sterilized by dipping in 95 per cent alcohol 2 or 3 times—each time allowing the alcohol to burn. The inoculating culture should be heavy enough to produce a complete film of growth, with no separate colonies visible. If bacteriophage is present, plaques will show in the bacterial film on the surface of the plate. Sometimes, however, a very active bacteriophage may completely inhibit growth, and there will be practically no colonies on the plate.

2. Another method is to smear a loopful of broth from the doubtful tube and another loopful from the control, each on separate spots about 1 cm. in diameter or larger on an agar plate. Lysis will be indicated by (1) no growth; (2) a scanty growth; or (3) plaques in the bacterial film. The amount of reduction in growth can be determined by comparing with the control.

3. The third way to check up on tubes showing no clearing is to seed thoroughly the surface of an agar plate with the organism. Then with a loopful of material from the tube make a circle on the surface of the agar. Make one also with the control for comparison. If bacteriophage is present, it will be indicated on the ring by more or less inhibition of growth of the organism or by a few well defined plaques. Usually the bacteriophage particles are much more numerous at 18 to 24 hours than the resistant organisms which have begun to grow out, and the latter do not interfere materially in interpreting the results on the plates.

ISOLATION WITHOUT FILTRATION

It is possible to isolate bacteriophages without filtering the material from the stool through a Berkefeld filter. The percentage of isolation will not be high, however, since only the most active ones

will be recovered in the presence of the rapid growing and spreading bacteria or of the spore forming organisms which will be encountered in stools. The stool specimen should be placed in contact with broth as outlined above, and 0.5 c.c. of the broth placed in an 18 hour broth culture of the organism causing the outbreak. After 12 to 24 hours incubation, the tube is placed in a water bath and the temperature held at 60° C. for ½ hour. This will usually kill the vegetative bacteria and not harm the bacteriophage. A very small loopful of the material is then placed in an 18 hour broth culture of the organism and immediately plated out as described above. The presence of bacteriophage will be shown by plaques or by complete inhibition of growth.

SPECIFICITY OF BACTERIOPHAGES

The bacteriophages isolated in this study were brought to full activity by serial transplanting in broth cultures of the susceptible organism and then filtering. The filtrates were placed in contact with the organisms named in Table I plus the 5 English strains of Flexner dysentery bacillus (V, W, X, Y, and Z). One drop of filtrate and 1 drop of broth culture of the organism is placed in a tube of broth. Controls receive only the organism.

A great deal of labor was saved by using special metal battery boxes, each holding two rows of 10 tubes each. These were modified from similar ones described by Wells,³ the principal change being to leave the lower 2 inches of the tubes exposed instead of the middle, and to increase the number of tubes from 10 to 20 per box. These boxes eliminated handling cotton plugs when filling the tubes as well as when inoculating them. One row of tubes can be lifted up with a special lifter while observing the other. In using the boxes a separate row was used for each organism, 9 tubes receiving bacterio-

phages and the 10th being left as a control.

Another time-saving apparatus was devised to fill the tubes of broth more rapidly. It consists of a glass syringe and a special valve connected with a reservoir which automatically measures out the proper amount of broth when a tube is pushed against the bottom of the valve.

The tubes were left at room temperature for 18 to 24 hours. Incubation at 37° C. causes the resistant organisms to grow out more rapidly, and frequently tubes which have cleared within 6 to 12 hours will again become turbid by the end of 24 hours. At the end of 24 hours all tubes and controls were plated out on agar in numbered squares corresponding to the numbers of the tubes in the protocol. Sixteen to 20 squares can be marked off on a plate. An area about 1 cm. in diameter is evenly covered with a small loopful from each tube. Frequently bacteriophages are found on the plates which would have been missed because of failure of the broth tubes to become clear.

SUMMARY

In outbreaks of bacillary dysentery bacteriophages active against the organism causing the outbreak were isolated from the stools of 60 to 80 per cent of those showing clinical symptoms, when stools were obtained during the second week after onset.

In outbreaks due to other causes bacteriophage isolation did not yield any useful information.

Outbreak of Milk Poisoning Due to a Toxin-Producing Staphylococcus Found in the Udders of Two Cows*

JAMES A. CRABTREE, M.D.,

AND

WILLIAM LITTERER, M.D., PH.G., F.A.P.H.A.

Director, Division of Preventable Diseases, and Director, Division of Laboratories, Tennessee State Department of Public Health, Nashville, Tenn.

SO far as the authors are aware, Barber (1914) first suggested that a toxin-producing staphylococcus was responsible for cases of food poisoning, when he described cases of gastro-enteritis which had occurred from time to time (1909-1913) on a certain farm in Nueva Ecija Province, Luzon, P. I., and attributable to the ingestion of improperly refrigerated milk which contained staphylococci in abundant quantities.

During the past three or four years outbreaks of food poisoning due to staphylococcus "enterotoxin" have been reported by a number of investigators, notably Jordon, and indeed the splendid work of Jordon and his associates has stimulated a widespread interest in the problem.

This report refers to a series of outbreaks of acute food poisoning occurring at Pleasant Hill Academy, Pleasant Hill, Tenn., from time to time during the period July 27-October 20, 1933.

Pleasant Hill Academy is a prepara-

tory school operated under the auspices of the American Missionary Association, and situated on the Cumberland Plateau in Cumberland County, Tenn., 90 miles west of Knoxville and 120 miles east of Nashville.

The school owns a farm of several hundred acres. A herd of 13 cows supplies all of the milk. Practically all of the labor at the school is done by the students. They work on the farm, cook, wait on table, fire furnaces, do janitor work, and operate the laundry.

The principal and his family reside in a separate house on the school campus, and the farm-manager occupies an apartment in one of the dormitories, and for these two families meals are prepared and served within their respective homes. The remainder of the faculty members and all of the resident students live in the dormitories and eat in one dining room, the arrangements being such that one faculty member is placed with each table of students. Thus, with the exception of the principal and farm-manager, the faculty and student body have the same food supply.

During the period June-August, 1933 (school vacation), the only persons who lived on the school premises were the

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 5, 1934.

families of the principal and the farm-manager and 2 students who helped with the operation of the farm and dairy, these students staying in the dormitory and boarding with the farm-manager.

On July 27, 1933, cases of acute poisoning occurred in all of the 6 members of the household of the farm manager, including the 2 students. Clinically, the cases were characterized by acute and sudden onset of nausea and vomiting, and in some instances prostration. Purging and diarrhea did not occur in these cases, but were prominent symptoms in later outbreaks. All cases were reported to be afebrile, and recovery rapidly followed emptying of the stomach. All of the cases had onset within 15 minutes of each other, the time being about 10 a.m., or approximately 3 hours after breakfast.

School opened during the last week of August, 1933, when 88 resident students enrolled, and these, with 9 faculty members, made a total resident population of 97, ranging in age from 14 to 54 years, and including 51 females and 46 males.

On September 4, 1933, the second outbreak occurred involving 45 cases, all having onset at about 9 p.m., or approximately 3 hours after the evening meal. In this and in all subsequent outbreaks no cases occurred in the family of either the principal or the farm-manager. Subsequent outbreaks occurred on September 13, 20, 27, October 2, 10, and 20.

It is interesting that the 7 outbreaks which occurred following the opening of school were rather evenly distributed with respect to time, the intervals between successive outbreaks ranging from 7 to 10 days.

A total of 242 cases occurred, 233 in students and 9 in faculty members. Students suffered an attack rate 2.9 times that of faculty members, the rate for the former being 2.9 cases per person and for the latter 1 case per person. In 2 of the outbreaks the approximate hour of onset of cases was 9 p.m. and for the remaining 5 was 10 a.m.

Table I shows for each of the 7 outbreaks the date, the approximate hour of onset of the cases, and the number of

TABLE I

DATES OF OUTBREAKS OF FOOD POISONING, APPROXIMATE HOURS OF ONSET OF CASES, AND NUMBER OF CASES WITH CASE RATES IN STUDENTS AND FACULTY MEMBERS AT PLEASANT HILL ACADEMY, TENN.—SEPTEMBER 4–OCTOBER 20, 1933

Date of Outbreak	Approximate Hour of Onset	Number of Cases			Case Rate (=100)		
		Students	Faculty	Total	Students	Faculty	Total
Sept. 4	9 P.M.	44	1	45	50.0	11.1	46.4
" 13	10 A.M.	30	2	32	34.0	22.2	33.0
" 20	10 A.M.	15	0	15	17.0	—	15.5
" 27	10 A.M.	25	1	26	28.4	11.1	26.8
Oct. 2	9 P.M.	34	2	36	38.6	22.2	37.0
" 10	10 A.M.	16	0	16	18.2	—	16.5
" 20	10 A.M.	69	3	72	78.5	33.3	74.5
Total		233	9	242	290.0	100.0	250.0

cases with case rates in students and in faculty members.

The explosiveness of the outbreaks, with all cases having onset within 15 to 30 minutes of each other, indicated that the etiologic agent was transmitted from a common source; and the consistency with which onset of cases occurred 3 hours following a meal further indicated that food was the most probable vehicle.

The absence of temperature, the abrupt and violent onset, the short duration, and rapid recovery without material after-effects all tended to indicate that the illness was due to a toxemia or poisoning rather than an infection.

The cases were not reported to the State Health Department until October 3, on the morning following the 5th outbreak. Investigation was made by one of us (J. A. C.) at that time, when epidemiological case records were obtained for all of the cases which had occurred previously. Subsequent cases were investigated within less than 24 hours following onset.

In the students the distribution of cases with respect to sex and age was in no way unusual. In the faculty members, the numbers were too small to justify comparisons.

Since a total of 242 cases occurred in 97 persons, it would follow that a number of persons suffered repeated attacks. The distribution of persons according to the number of attacks is shown in Table II.

TABLE II
DISTRIBUTION OF ATTACKS

Number of Attacks	Number of Persons	Per cent of Total
5	12	12.4
4	16	16.5
3	19	19.6
2	26	26.8
1	9	9.3
0	15	15.4
	97	100.0

Because of the practice of the school of assigning one faculty member for each group of students at a table, both students and faculty members ate the same food, which was served and prepared by the same people.

Information was obtained as to the various articles of food consumed by each of the 97 persons at the meals immediately preceding onset of the cases.

With the exception of milk, no article of food eaten during these meals appeared more frequently in the diet of those ill than of those not ill.

Table III shows for each of the outbreaks the number of cases, and case rate in persons who drank milk during the meal immediately preceding onset of cases, and for comparison the attack rate in those who did not drink milk.

Out of the 242 cases, all but 1 occurred in persons who had drunk milk during the meal immediately preceding onset. The attack rates in milk consumers varied from 17.6 per cent on September 20, to 81 per cent on October 20. In view of subsequent data which clearly established the fact that milk was the vehicle of the causative agent, it is quite likely that for the case occurring in the person who denied drinking milk, either the history was unreliable, or perhaps the illness may have been of another nature.

Following the outbreak of October 2, fecal specimens from all of the 37 persons who were in any way connected with the handling of food were examined for the typhoid, dysentery, and salmonella group of organisms with entirely negative results.

Following the outbreak of October 20 all articles of food served at the meal immediately preceding onset, and also pooled specimens of first vomitus of the patients were examined both bacteriologically and chemically. In addition, specimens of throat secretions from all of the food handlers were immediately streaked on rabbit blood-agar plates and

brought into the laboratory for bacteriological examination. The articles of food included cereal, sugar, toast, coffee, milk, bacon, scrambled eggs, apple sauce, and butter. The chemical examination* included a search for arsenic, lead, strychnine, mercuric chloride, barium and antimony salts, phosphorus, and various alkaloids. Results of chemical analyses were entirely negative.

In the bacteriological examination, each article of food and the vomitus were examined directly by stained smear (Gram) and a loopful was planted for culture on plates of plain agar, Endo's, eosin-methylene blue agar, and 3 per cent rabbit blood-agar.

All of the articles of food except milk contained only very few bacteria, and these were of various types.

From the milk and the vomitus, hemolytic staphylococci were obtained

in enormous numbers and practically in pure culture. The staphylococci were decidedly hemolytic and were of both the albus and aureus types, the ratio of aureus to albus being about 40 to 1.

Of the 37 food handlers whose throat secretions were planted on rabbit blood-agar plates, 12 showed large numbers of hemolytic staphylococci, both aureus and albus, the aureus predominating in a ratio of 50 to 1. Incidentally, all of these 12 persons had suffered attacks of poisoning less than 24 hours before the specimens were obtained. These 12 persons were reexamined at 3 day intervals during the following 3 weeks, and in all of them the organisms had disappeared apparently by the end of this time. Each succeeding examination showed a diminished number of organisms, and in all but 3 persons, results of examinations were negative at the end of 12 days.

The staphylococci recovered from the milk, the vomitus, and the throat secretions of the food handlers were tested for production of toxic products, the

* Chemical examinations were made by Dr. J. W. Sample, Chief Chemist, Tennessee State Department of Agriculture, Nashville.

technic employed being that described by Woolpert and Dack (1933).

In testing for the presence of enterotoxin substance in the filtrates from these organisms only human volunteers were employed. Three c.c. of filtrate in approximately 3 ounces of pasteurized milk were given to persons who had not eaten any food for more than 5 hours. Where illness followed the ingestion of these filtrates, the incubation period was shorter (though somewhat variable for different filtrates), and symptoms were less severe, but otherwise clinically identical with those occurring in the outbreaks.

Although a sufficient number of human volunteers could not be obtained to test all of the filtrates that were prepared, some of the organisms recovered from the milk, the vomitus, and the throat secretions of the food handlers were tested.

The yellow staphylococci recovered from the milk, the vomitus, and from 5 of the 12 food handlers proved to be toxin-producers, the filtrates producing illness in all of the human volunteers. Filtrates from the organisms isolated from the milk and the vomitus produced symptoms within 30 minutes, but those from the 5 food handlers produced illness with incubation periods ranging from $1\frac{1}{2}$ to 3 hours.

In these tests, 8 persons were used as controls, these being fed milk and sterile media, and none of them became ill.

All epidemiological evidence, supported by bacteriological findings, indicated that milk was the most probable vehicle of the "enterotoxin." However, it was necessary to determine the source of the organisms which apparently produced the "enterotoxin"; i.e., whether the secreted milk itself contained the organisms, or contamination occurred through handling of the milk by one or more infected food handlers. The latter possibility was suggested by the fact that 12 of the food handlers

were found to harbor the organisms in their throats.

Beginning October 23, specimens of milk were obtained under as nearly aseptic conditions as possible from each of the 13 cows, at a rate of 3 specimens per week (every other day) for a period of 5 weeks. During this period, specimens from 2 cows (Nos. 2 and 7) showed almost consistently a large number of hemolytic staphylococci. Specimens from 4 other cows occasionally showed the organisms, but filtrates from these when fed to human volunteers failed to demonstrate enterotoxin substances in 50 c.c. amounts.

Of the 12 specimens from cow No. 2, 9 contained hemolytic staphylococci, and from Cow No. 7, 12 of the 15 specimens were positive. Both the aureus and albus types were found in the milk from each cow, the aureus predominating in proportions, ranging from 25 to 1, to 60 to 1. Filtrates from the albus produced no symptoms when fed in 50 c.c. amounts to human volunteers. Filtrates from 7 different aureus cultures produced illness in 12 of 15 human volunteers when fed in 3 c.c. amounts.

The number of organisms to the c.c. of milk from cow No. 2 averaged about 2,900, and from cow No. 7, about 4,500. One specimen showed a count as high as 17,500, while others contained only a few. A negative specimen would usually be followed by a tremendous increase to the maximum bacteria count. Table IV shows the results of examinations of the various specimens of milk taken from cows Nos. 2 and 7 over the 5 week period.

Evidently somewhere in the udders of these 2 cows there were pus pockets which would occasionally break loose, producing a "showering" of staphylococci, followed by a gradual diminution in number of organisms for a time, after which another "showering" would take place. This recurrent "showering" of organisms is of particular in-

terest in view of the recurrent and more or less evenly spaced outbreaks of poisoning.

These 2 cows were examined by a veterinarian who stated that they had "Garget" or mastitis which is a chronic infectious disease characterized by recurrent acute attacks when the cow is drying off, when she freshens, when she is fed heavily on a high protein diet, or when she is otherwise exposed to unusual strain. If the disease is acutely active, the milk may be changed in appearance. The milk from both of these cows was at times ropy and stringy, containing red blood cells and numerous

pus cells. From cow No. 7, the milk on two occasions showed the presence of macroscopic blood.

The school dairy consisted of 13 cows, tuberculin tested annually and apparently in good physical condition. The dairy barn is of reasonably modern construction, with individual stalls for the cows, cement floor, and ample water supply.

The milking is done by hand, by 5 boys who are students at the school. Generally speaking, sanitary precautions concerning the milkers, the cows, and the milk utensils could be regarded as satisfactory.

Each milker used an ordinary 1 gallon milk pail from which the milk was transferred, at the dairy barn, directly into 5 or 10 gallon cream cans. In this transfer the milk was strained through clean cheesecloth.

With the exception of that which went to the residences of the school principal and farm-manager, all the milk was carried from the barn to the kitchen (in the girl's dormitory) in these large cream cans, and stored in these containers until it was served. The kitchen contained two refrigerators, one an ordinary commercial Frigidaire and the other a built-in cold storage room, both being refrigerated by means of one electrical motor located in the basement of the kitchen. The cold-storage room was used largely for the storage of meat and these large containers of milk. The temperature in this room was considerably higher than that in the commercial Frigidaire.

The milk which was brought in at night was stored over night and served the following morning. The morning's milk was usually served at the evening meal.

The milk which went to the residences of the school principal and farm-manager was carried directly from the dairy barn to the residences in the small milk pails, transferred to milk con-

tainers and immediately placed in the refrigerators in the respective residences. Because of the much smaller milk containers and the lower temperatures in the refrigerators, the milk for the families of the school principal and farm manager became chilled very much more quickly and was brought to a lower temperature than that stored in the large cream cans and served to the rest of the resident population. This rapid chilling presumably inhibited the growth and toxin-production of the staphylococci present in the secreted milk, and therefore offers the most plausible explanation of the fact that no case of poisoning occurred in any member of these two households, notwithstanding the use of milk from the same cows that supplied the rest of the faculty and student body.

Recommendations to the school authorities embodied removal of 2 of the cows from the herd, and measures directed toward improvement of re-

frigeration facilities. These recommendations were put into effect immediately, and no additional cases of poisoning have been reported to date.

DISCUSSION

We believe that this is the first recorded outbreak of poisoning due to enterotoxic products of the staphylococcus where it was possible both to identify the enterotoxic substance, and to determine the source of the staphylococcus.

The circumstances under which the outbreak occurred merely add to already overwhelming evidence supporting the need for rigid sanitary control of milk supplies.

Maternity Benefits in Cuba

A DECREE signed by the President of Cuba on April 18, 1934, prohibits the employment of women for 6 weeks following confinement. The prohibition applies to all establishments, whether industrial or commercial, public or private.

According to this decree a pregnant woman is permitted to leave her employment 6 weeks before the probable date of childbirth, upon presentation of a physician's certificate. For the duration of her absence from work the woman is to receive a cash benefit equal to her wages, paid from an insurance fund to which the State, the employers, and the women workers will be required to contribute. Attendance by a physician or midwife will also be provided.

An employer must permit every nursing mother to have two daily periods of half an hour each in which to nurse her child, exclusive of the rest periods provided by law.

Pregnancy or illness connected with it must not constitute a cause of discharge, unless the woman's absence exceeds the time allowed for that purpose.

No pregnant woman may be employed on strenuous work or on work that may interfere with the normal development of the child.

Every industrial or commercial establishment employing 50 or more women must provide a day nursery for employees' children under the age of 2.

Fines are provided for violations.—*Gaceta Oficial de la Republica de Cuba*, April 20, 1934.

Health Hazards in the Oil Industry*

R. A. JEWETT, M.D.

Medical Director, General Petroleum Corporation of California, Los Angeles, Calif

OIL is the miracle worker of our modern world, satisfying man's needs, not only in meeting demands of commerce and recreation, but furnishing heat, light, power, transportation, lubrication, cleaning, insect extermination, and medicines—a field, our chemists tell us, the surface of which has been only scratched. What a challenge to them!

The industrial hygienist receives the same challenge, for the possibilities of health hazards are many in the oil industry with its numerous and diversified processes. The literature on this subject reveals a wonderful lack of actual hazards; but the potential possibilities remain, nevertheless, when an analysis of the individual and varied operations is made.

Four major divisions of the oil industry combine to bring the oil and its various products to the public.

1. *Production* with its geological, drilling and pumping operations
2. *Transportation* with its pipe lines, pump stations, ships with their terminal facilities, automobiles with their garages and shops, and railroad tank cars
3. *Refining* with its stills, natural gasoline, grease, and other plants, tank farms, test and research laboratories
4. *Marketing* with its storage tanks, warehouses, and service stations

There are the usual service divisions necessary for the conduct of business on

a big scale. However, the employees in these divisions are office or shop workers primarily, and are not subjected to the health hazards characteristic of the major divisions, which are our chief concern.

There is one hazard common to all the major divisions, namely, gas vapors and fumes which are given off by the oil and its products. The effect of these is not so much incipient and cumulative, as it is sudden, due to the nature of the poisons in the gases and vapors.

First, we have the higher hydrocarbons—methane, ethane, propane, the butanes and, to a lesser extent, the lower hydrocarbons. The higher group, under certain conditions, are harmful to health. Some act as asphyxiants, others as irritants, and even in small quantities are poisonous. Those of the lower group may be similar in their action, but do not directly affect the body tissues or the delicate structure of the lungs; and produce no evidence of anything suggesting chronic poisoning, even when inhaled in considerable quantities day after day. Possibly the reason for this is that these lower gases are chemically inert and lacking in tendency to promote organic decay.

These hydrocarbons are found more in natural gas and refinery gas than in crude petroleum. Their composition is related to the temperature, consequently appreciable quantities cannot be present until the temperature is near the boiling point. An atmosphere containing more than 0.2 per cent of hydro-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 4, 1934.

carbon gas or vapor may be considered as dangerous.

We may have hydrogen sulphide in petroleum or its products, and here is a real health hazard, for its poisonous effects are well known, even when the air contains only 0.0005 per cent. Fortunately, this gas is encountered in but few of the oil districts. The proportion is ordinarily under 1 per cent, but as high as 15 per cent has been found. The light oils in Mexico have the highest percentage. Those in Ohio and the mid-continent fields have considerably less, while scarcely any is found in the oils in California.

Carbon dioxide, of course, is here, there, and anywhere, because it is the chief product of complete combustion. It is found, primarily, at all wells in flue gas, and in wash gas from furnaces and engines. This gas is not considered as containing poison which is deleterious to health but it will surely put one out if he gets enough of it, and not infrequently, the recipients remain sick for days.

Unlike carbon dioxide, carbon monoxide is one of the most insidious of the poisonous gases encountered in the oil industry. It is produced in the burning of carbon containing materials such as natural gas, coal, coke, wood, or gasoline, whenever the supply of air is not sufficient for complete combustion. Due to the outdoor nature of the oil industry and proper disposal of the waste from the furnaces and engines, concentrations of this gas are not likely to occur. Automobiles on the move and garages present the most serious hazards, but so much has been written about carbon monoxide in relation to the automobile, it is not necessary to review the subject here. I refer you to the *Travelers Standard* (Vol. XXII, Mar. 3, 1934).

Sulphur dioxide is a product of combustion when sulphur or any fuel containing sulphur or sulphides is burned,

and is the chief irritant present in flue gases when natural gas or any gas containing hydrogen sulphide is used as a fuel. It is also formed when coal is burned, and when lubricating oils are treated with sulphuric acid. It is used as a treating agent for the purification of gasoline, naphtha, kerosene, and lubricating oils, so is primarily used in refineries. It is handled in cylinders, as it is poisonous if over 0.004 per cent, but it is so irritating to the eyes and lungs in small concentrations that a person coming in contact with some of the escaped gas will get out of it before he experiences any poisonous effects.

From a detailed review of the chemistry of these gases, which is not permissible in so short a paper, it must be concluded that the hazard is primarily that of irritation and asphyxiation even with the more poisonous ones. Whether there is any detrimental cumulative effect on normal or pathological body tissues, or an aggravation of an existing condition from the inhalation of these gases in small quantities over a period of time, is a question to which there is no satisfactory answer. The literature is almost nil—expressions vague—which indicate that little research has been done.

As the compensation laws in the various states are changed to make industry responsible for industrial injuries, including the aggravation of existing physical conditions, as they are in California, the answer will be forthcoming. In this connection, let me cite a case under my personal observation of an employee who had worked 8 years as a mechanic. His duties required him to repair pumps in the pipe line stations. In working on the opened pumps he would be more or less exposed to the oil with its fumes and vapors. He developed a chronic nephritis, and after he died, his family brought claim under

the Workmen's Compensation Act for the total amount of the death disability, which under the California Law is payable if death results from the aggravation of an existing condition. Also, under the law, an employee only has to state he is injured, and the company pays unless it can prove he is not. I had a pump opened in order to reproduce the conditions under which he worked; had the gases and vapors analyzed; the amounts of the various gases in the air measured as to volume at various levels from the floor to the ceiling; made diagrams of the station showing method of ventilation, and air space; secured copies of our instructions to employees as to what to do when working in gases and vapors; had fellow workers in his crew ready to testify that claimant knew the instructions and observed them. I then sought the opinions of medical specialists, some of them with much experience in the oil industry, as to whether or not these conditions as stated could produce or aggravate a nephritis or any other kind of an "itis" in the human body. The consensus of opinion was that the gases and vapors were only irritating and anesthetic in action, and would not aggravate existing physical conditions.

At the trial, the claimant's attorney introduced evidence to show that the company had exposed his client to petroleum fumes and vapors, and then introduced exhibit "A"—a pamphlet issued by the U. S. Public Health Service, which dealt with the subject of Poisonous Effects of Benzol in Petroleum on the Human Body. He stated that the Service was the highest authority and most expert on such subjects, and rested his case. It was a simple matter to put our chemist on the stand, who testified there was no benzol in the petroleum or its gases passing through our pipe lines, although it was found in some oils outside of California. No evidence of poisoning

by other elements was introduced, so nothing was proved or disproved.

In considering the petroleum vapors and gases as a health hazard, let us not overlook the menace due to their explosive characteristics.

Another hazard common to all the major divisions is the production of skin rashes, blebs or pustules from direct contact with the oil or its products. This affects employees in varying degrees—some not at all, while others cannot be allowed to work in contact with the oil, and especially the distillates.

Let us now consider separately the hazards incident to each major division:

PRODUCTION

If you stand on the floor of an oil rig while drilling is in operation, you are impressed with the possibilities of the accident hazards. But what about the health? Well, the men seem healthy for they are out in the open, but they are out through wind or rain, heat or cold, day or night, and, theoretically, such exposure is certainly not conducive to good health.

We know noise is detrimental to the sense of hearing is fatiguing, is depressing to the nervous system. At times, gas escapes from a well for hours, and the men have to work in this roaring sound even though they can keep clear of the gas fumes, and this may have a decided and often a prolonged effect on hearing, in some cases.

The repeated removal of foreign bodies from eyes is detrimental to sight, but frequent washing of the drill pipe and greasing of the cables has minimized this hazard.

The pumpers, or those employees who service the wells after they are on production, are, I believe, quite free from health hazards except those due to natural elements. Regulation of health habits cannot be maintained due to the shift work. This is also true of most of the workers in the major divisions.

TRANSPORTATION

In this department, the main hazard is exposure to the fumes and vapors. Storage tanks, reservoirs, railroad tank cars, holds of oil tankers, pipe lines and their pumps have to be cleaned. Opening them up to fresh air, washing them down, steaming them out—experience has taught us—is not enough. This is usually done by opening a small man-hole in the top, over which the gauger stands and may inhale fumes. The full tank is not the dangerous one—but beware of the partly filled tank. There is room for the accumulation of plenty of gas. Leaking valves or cracks in the casings are sources of exposure usually unknown and unseen. An additional hazard in this department is dust from filings and scaling resulting from cleaning the pipes and tanks.

REFINING

Add to the gases and vapors already described, ammonia and chlorine. Then we have a list of the gases and vapors with which refinery workers may come in contact. What has been said about the danger of them can also be said about ammonia and chlorine—namely—they are primarily accident hazards, and not health hazards as we know them, but ammonia will produce a chronic catarrh if inhaled with air in a proportion over 0.15 per cent. Keep these gases and vapors in their containers by preventing leaks, and by proper vents in the pipes, stills, tanks, and ovens; and by the wearing of properly selected gas masks when the employees do encounter them, and you will have safe and healthy refinery workers.

However, there are other materials used which may prove to be a health hazard. I refer to sand, lead, paraffin, tar, acids, and alkalis. Sand is used in cleaning, as sand blasting; although I believe this method is being increasingly discontinued. The effect produced by inhaling sand particles is known as

silicosis, which is a subject in itself. The method of its use and control is well described in a pamphlet, *Safeguarding Sand Blasting Operations*, issued by the Standard Oil Company of New Jersey under date of February 9, 1934.

Recently, lead which is well known as a health hazard has been introduced into the industry in the form of tetra-ethyl lead. It proved to be a real hazard, and in the beginning caused several deaths in the manufacture and blending process. This cannot be charged to the oil industry, however, as the manufacturing is done by a special corporation. The finished product is received at the refineries in tanks, and under supervision of the Ethyl Gasoline Corporation is mixed into the gasoline by specially selected workers. The process is so automatic that the amount of vapor to which an employee is exposed is negligible. However, every precaution is taken by the employee as instructed by the Ethyl Corporation.

Crude oil and all the distillates may be contacted by the refinery worker. These products affect the skin to a greater or less degree. Usually a simple irritation is first produced, or there may be furuncles, papillomata, plaques, and even skin cancers are reported. The lower distillates, paraffin and tar, are the greatest offenders in producing real skin lesions; while the higher ones give rise to skin dryness, cracking, and simple dermatitis.

We cannot leave the refinery without mentioning that acids and alkalis are used in the preparation of petroleum products, but these are not volatile, and so no real health hazard; but do cause many burns, so again we have the accident hazard.

MARKETING

Lead chloride, bromide, and sulphate result in the form of dust from com-

bustion of ethyl gasoline. Does this produce a health hazard to the drivers of cars, to garage men, and mechanics working in cars using ethyl gas, and to the public? Extensive researches have been carried out by the Kettering Laboratory of Applied Physiology, and the results of their experiments are described in their pamphlet, *An Appraisal of the Lead Hazards Associated with the Distribution and Use of Gasoline Containing Tetraethyl Lead*. These results lead one to the conclusion that this hazard is negligible to garage attendants and mechanics; so practically nil to service station attendants and the public.

The only other hazard I have observed in the marketing division is irritation of the eyes of service station attendants which is caused by acids used in cleaning the springs of cars, and the use of trisodium phosphate for cleaning about the stations, especially the lubricating racks.

Health problems which are common to all employees in the oil industry, as well as to employees of other industries, deserve special consideration, although time will not permit of a full discussion. However, I want to mention 3—the common cold, vision, and syphilis.

A few years ago I offered our employees free inoculation with the Mixed Respiratory Vaccine. About 1,000 of the 6,000 employees have taken it, all of whom stated they were subject to colds. Of that number, 75 per cent report that they have had no colds since; 12 per cent that their colds have been fewer and less severe; and 13 per cent report no benefit. In reviewing my physical examinations of the no-benefit group, I discovered that nearly all of them were suffering from some form of chronic infection, such as sinusitis, rhinitis, pharyngitis or bronchitis. The conclusion, therefore, as to the real value of the vaccine is obvious.

For years I have been impressed by

the great amount of relief obtained from physical symptoms by proper treatment of the eyes. Early in my medical program I had an eye survey of the employees made by a doctor specializing in sight conservation and industrial illumination. He reported:

	Per cent
Normal vision	70
Subnormal vision	30
Pathological eyes	7
Recommended for vocational placement	2
Wearing glasses	22
Wearing glasses properly fitted..	42
Wearing glasses improperly fitted	58

Again the conclusion as to the real value is obvious.

Three years ago I included a Wassermann test as part of the physical examination, and 3.4 per cent of the employees gave a positive reaction. Of the number positive, 32 per cent admitted knowledge of infection, and 68 per cent denied any knowledge of infection. From my talks with the ones denying any knowledge of infection, I believe they were, with possibly 2 exceptions, sincere in their belief. From what we are told this is indeed a low per cent of positives, but it does mean that 2 per cent of the oil workers have syphilis who do not know it.

To tell a wage earner in these times of small wage income that he needs treatments for syphilis is creating a mental hazard unless treatments are offered at not more than the cost of medicine and materials used. Furthermore, the majority of cases are past 40 years of age, married, and have families. Thus, social as well as mental and financial problems are created. Only 4 per cent of my cases refused to take treatment, and among those treated, the reduction of the positive Wassermann findings has been indeed discouraging: so I present you the problem. What are we going to do about finding and treating the employee infected with syphilis?

Conclusions to be drawn from this paper certainly are that health hazards in the petroleum industry are few and are easy to control. The more important hazards are due to the natural elements, and the method of working the employees. Chemical poisons are pres-

ent in the form of gases and vapors, but they are more of an accident hazard than a health hazard.

Health problems outside of health hazards give the physician working in the oil industry a larger field of activity.

Simon Baruch Laboratory at Saratoga Springs

A NOTABLE company of physicians and men and women in public life gathered at Saratoga Springs, N. Y., on September 14 to witness the laying of the corner stone of the new Research Laboratory of the Saratoga Spa. Governor Herbert H. Lehman, who presided at the ceremonies, gave the laboratory the name of Dr. Simon Baruch, a pioneer in hydrotherapy in this country and professor of hydrotherapy at the College of Physicians and Surgeons for many years. The Saratoga cardiac therapy was based upon studies of European spas and long clinical experiment by Dr. Baruch. Dr. Herman B. Baruch, his son, laid the stone.

Dr. John Wyckoff, Dean of New York University-Bellevue Medical College, was the orator of the day. He stressed "the purpose and the value of an establishment such as is being developed here in Saratoga, in its relation to chronic illness."

Completed and equipped, the Simon Baruch Research Laboratory will represent an investment of \$750,000.

The Baruch Laboratory will be ready for use in 1935. It is one of the monumental group of buildings, all in process of construction, now going up at the Spa and which will, together, cost in excess of \$5,000,000. These buildings include the Hall of Springs, whose corner stone was laid in July, 1933; a new bath house of distinctive design and purpose, a hotel with sanitarium facilities, a new plant for the bottling of Geyser, Hathorn, and Coesa waters, and a recreation center, at which the remedial uses of sports will be stressed.

Pierrepoint B. Noyes, of Oneida, N. Y., is chairman of the Saratoga Springs Commission. Its medical members are Dr. Carl R. Comstock, of Saratoga Springs, and Dr. L. Whittington Gorham, of Albany.

Public Health Aspects of Dried Foods*

PAUL F. NICHOLS

University of California, Berkeley, Calif.

WHETHER drying or cold storage is the older method of food preservation used by man is a matter of speculation. Certainly both methods must have been practised in prehistoric times, and antedate any of the other methods now employed. The methods are also similar in fact that in modern times their use has been extended to new products through the use of new principles and new equipment. From the point of view of continuity of employment and essential stability of method, drying must be regarded as an eminently useful art in the advancement of human society.

Broadly speaking, we may consider drying as applicable to all classes of foods, including grains and spices. Usually we do not include the grains which ordinarily dry spontaneously without requiring special control of the process, nor do we include spices which, though often preserved by drying, have little direct nutritive value and may often be used to assist in the preservation of other foods. Between these extremes of usefulness all the other essential foods may be and are extensively preserved by controlled processes of drying. The list includes fish, meat, milk, eggs, fruits, and vegetables.

In view of its wide application, the public health significance of drying is naturally of interest. While dried foods

appear not to have been as widely investigated as have canned or fresh, numerous bacteriological studies have been made. The relatively few studies that have been made upon dried fish and meat, and the larger number on dried milk have been ably summarized by Tanner.¹ It should be noted that the drying of fish and meat is, as a method of preservation, usually augmented, if not eclipsed, by the use of the preservatives, salt or smoke. It should also be noted that salt and some of the components of smoke are admittedly toxic by themselves or when consumed in sufficient amount, but when used in the customary manner are regarded as entirely innocuous and even desirable by consumers and health authorities. A preservative is also used in the drying of fruits and this introduces considerations that will be discussed in some detail. In the drying of milk, eggs, and vegetables on the other hand, chemical preservatives are not used.

Comparatively little bacteriological study has been made of dried fruits and vegetables. Most of this has been done by Prescott^{2, 3, 4, 5} and his coworkers, and by Fellers.⁶ As a rule only small numbers of organisms have been found when the products were in good condition, and these were of harmless types. A tendency for the organisms to die off on prolonged storage has been observed. While but little work has been done on the survival of pathogenic bacteria the indications are that danger in this respect is remote.

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-third Annual Meeting at Pasadena, Calif., September 6, 1934.

It is presumable that the drying process itself as well as the treatments that often precede or follow it tend to kill microorganisms. A brief description of the drying methods for fruits and vegetables, together with reference to investigations made, may justify this statement. Of the comparatively small quantities of vegetables now being dried in the United States, all are dehydrated for periods of 6 hours or more, and the products are usually exposed for 1 hour or longer to temperatures of 150° F. or above.

The best dehydrated vegetables are steamed for 1 to 3 minutes before dehydration, though some are dried raw; none are sulphured. Among fruits only seedless raisins are customarily sun dried without some treatment with steam, hot water, or sulphur dioxide before or after drying. A few raisins are dipped in boiling lye solution before drying, and a few are both lye dipped and sulphured, followed by sun drying or dehydration. While seeded raisins are sun dried without pretreatment, the seeding process involves first dehydration, then treatment with boiling water or steam. Some figs are sulphured before sun drying, most are dried in the natural condition, but all types are ordinarily processed in boiling water for 1 to 4 minutes just before packing. Apples are sulphured and evaporated at temperatures usually exceeding 150° F.; many are later moistened and resulphured when packed. Prunes are dipped in boiling lye for a few seconds before sun drying or dehydration. When packed they are processed in boiling water for 2 to 5 minutes. Apricots, peaches, and pears are sulphured, then sun dried, and they are washed and resulphured when packed. Only the "natural" seedless and cluster raisins are packed without undergoing some more or less bactericidal treatment.

Of course there is no reason to sup-

pose that any of the treatments given to fruits and vegetables before, during, or after drying result in complete sterilization of the products. However, the general knowledge of time-temperature relations in the killing of microorganisms indicates that considerable reduction of the number of viable organisms may be expected from a few seconds' dip in boiling lye solution, a few minutes of exposure to boiling water or steam, a few hours in air at 140 to 160° F., or a few days of exposure to direct sunlight and temperatures of 120° F. or above.

The exact conditions employed by Fellers⁶ in pasteurization experiments are not met in the usual drying and packing processes, but the total counts observed by him in commercially packed American dried fruits compare favorably with the number of organisms found on pasteurized dates and figs. The writer has observed⁷ spoiling of unprocessed prunes at moisture contents as low as 18 per cent by yeast-like (as yet unidentified) organisms, while processed prunes did not spoil at moisture contents less than 22.5 per cent; all samples were held in sealed glass jars except when portions for chemical examination were removed. One explanation for this is thought to be that fewer viable organisms remained on the processed fruit, although this was not determined. As evidence of the bactericidal effect of sulphites, Cruess and Berg⁸ have found that 1,500 p.p.m. as SO₂ prevented fermentation of grape must for 2 years; this concentration is below that in many sulphured dried fruits. Also repeated attempts to isolate from adequately sulphured dried fruits microorganisms which had evidently been active before sulphuring have been unsuccessful at this laboratory. On the other hand molds growing on dried apricots containing SO₂ to the extent of 315 p.p.m. have been subcultured without difficulty. Molds have

been observed growing on dried pears containing 700 p.p.m. SO_2 . The last 2 cases represent instances of failure to give adequate sulphuring, which will be discussed below.

From the point of view of sanitation, it is unfortunate that in the United States fruits are not dried by dehydration as commonly as are vegetables. Because of the higher temperature employed and the reduced opportunity for contamination, dehydration is to be preferred to sun drying. Among fruits, however, only apples are generally dehydrated or evaporated. About 30 per cent of the prune crop of the country is dehydrated, about 7 per cent of the raisins, and only a negligible portion of the other fruits. A trade preference for sun dried apricots, figs, peaches, and pears exists, and the cost of sun drying these fruits is lower. For sun dried fruits the practice of processing by hot water or washing and resulphuring is desirable not only for cleanliness and improving the appearance of the products, but also for sanitary considerations.

The composition of fruits and the manner in which dried vegetables and most dried fruits are prepared for consumption are additional safeguards. The high acid and low protein content of fruits renders them unfavorable for the growth of most pathogens or the elaboration of toxins. Most dried fruits are cooked before they are eaten; dates, figs, and some raisins and prunes are exceptions. Of these, figs and prunes, as noted above, are processed in boiling water at the time of packing. The texture and flavor of dried vegetables render them unsuitable for use without cooking.

Dried fish and meat are for the most part cooked for consumption; when not cooked the preservatives used offer some protection. Dried eggs are practically always cooked. Dried milk is not always cooked and, since no preservative

is used in drying, the need for using safe milk in drying is apparent.

Dried fruits and vegetables are sometimes fumigated once or more to prevent development of insect infestation. Formerly hydrocyanic acid gas was used for the purpose, but at present this fumigant has been largely displaced by less toxic agents. According to the report of Williams⁹ the possibility of poisoning from fumigated dried foods, even when HCN is used, appears to be negligible.

On the whole, the public health record of dried foods is remarkably clear. The almost complete absence of food poisoning or infection cases in which dried foods have been involved indicates that they are among the safest forms of food. In an outbreak attributed to pudding made from dried peas¹⁰ there is evidence that contamination of the food took place after it was cooked. Two cases of poisoning from codfish cakes were investigated¹¹ and the causative organism identified, but the channel of infection was not traced; it seems possible if not probable that the contamination here also took place after cooking. An outbreak of colitis was traced to repacked dates¹²; here the culpability of the dried product seems established. Fifty-two cases of botulism have been reported from Russia¹³ of which about half were attributed to salted, dried, or smoked herring, salmon, or sturgeon eaten without cooking.

If this is a fair summary of the case against dried foods, considering the international nature of trade in dried fruits and the unsanitary methods sometimes used, they do not appear to be a serious health hazard. In this country the increasing use of machine-filled small containers and pasteurization offer increased protection to the public.

It is not claimed that the possibilities of infection or intoxication from dried foods in general have been covered in

this discussion. As a matter of fact, the chief interest and almost the whole experience of the writer has been in the problems that surround the drying of fruits and vegetables. In view of the failure of dehydrated vegetables to fulfill the promise of commercial development held forth by the stimulation if not creation of this industry during the World War, it may be well to dismiss dried vegetables also with the few remarks that have already been made.

There is a matter involved in the drying of fruits that seems to merit more extensive treatment than has usually been accorded it. There has been considerable discussion of it based upon prejudice or presumption, but the facts appear to have had more of avoidance than treatment. The point in question is the use of sulphur dioxide or sulphites in the drying of certain fruits, chiefly apples, apricots, peaches, and pears.

Sulphur dioxide is a chemical preservative. If it is to be used it must meet certain conditions from the standpoint of regulatory requirements. As used it must not endanger the health of the consumer, it must not be used for the purpose of concealing inferiority of the product, and it seems fair also to require that it be not used in amounts beyond those necessary to accomplish the purpose at hand.

The investigations of Rost and Franz¹⁴ and perhaps those of Wiley¹⁵ indicate that the ingestion of sulphites or sulphurous acid alone or in sufficient quantity produces toxic effects. On the other hand, the unpublished investigations carried out at the instigation of the U. S. Bureau of Chemistry between 1909 and 1914, and the more recent work in Germany reported by Flury,¹⁶ indicate that when consumed as a constituent of dried fruits, even in abnormally large amounts the preservative is without harmful effects. Flury compares the effects of sulphites to those of acetic acid, and points out that the

presence of sugar or pectinous materials with which the sulphites may be combined in the food appears to protect the body against harmful effects. The American Medical Association in an official publication¹⁷ has recently declared sulphites in dried fruits to be entirely harmless. As Flury points out, the constant use of sulphured fruits for years by the public and in hospitals and other institutions with close medical supervision has been attended by no discernible ill effects.

As to the second requirement it can be said that sulphur dioxide neither is, nor can be, used to conceal inferiority of dried fruits, if by that is meant the presence of decomposition or decay. It is true that high sulphur dioxide content will permit dried fruits to be held without spoilage at higher moisture contents than is possible without it. Existing tolerances set up by the U. S. Food and Drug Administration for moisture content in dried apples, apricots, and peaches appear to provide adequate protection against such an abuse, if it exists.

Approach to the third phase of the regulatory problem of the permissibility of sulphur dioxide may be made by asking the purpose of using this preservative and the amount required. The primary purpose is to preserve as far as possible the natural color of the fruit. The quantity required cannot be stated so simply, for it depends upon the degree to which the color needs to be preserved and is associated with other essential characteristics of the fruit, as well as upon the time for which the conditions under which the color is to be preserved. The work of Chace, Church, and Sorber,¹⁸ of Nichols and Christie,¹⁹ and many unpublished observations of the writer indicate that the best obtainable retention of color in California dried apricots is not consistently attained if the sulphur dioxide content is below 1,000 p.p.m.; commonly 2,000

or more are necessary and in some districts as much as 3,000 p.p.m. The usual method of sulphuring in California is to expose the cut fruit on trays to the fumes of burning sulphur in more or less tight sulphur houses. When this method is used, the amount of SO_2 absorbed by the fruit is not readily controllable within about 500 p.p.m. Nichols and Christie¹⁹ have shown that dried peaches and apricots lose half or more of their sulphur dioxide content when held in common storage for 6 months. It is also known that half or more of the sulphur dioxide disappears during cooking of the fruit. Nichols and Reed²⁰ in experiments with dried fruits originally of excellent color have shown that on storage the color of dried apples deteriorated so greatly that the fruit was regarded as unmerchantable when the sulphur dioxide content fell to about 200 p.p.m. A similar change took place in apricots and in pears at about 500 p.p.m. Therefore to provide for variations in season and district and for a factor of safety in case of prolonged storage, amounts of sulphur dioxide between 2,000 and 3,000 p.p.m. certainly do not appear beyond the range of necessity for apricots, peaches, and pears. Apples do not readily absorb these amounts, and require less for satisfactory retention of color.

In addition to its effect on color retention, its action on some of the vitamins is also pertinent. Morgan and Field^{21, 22} and Morgan, Field and Nichols^{23, 24, 25} have observed in the dried fruits they have studied that sulphur dioxide has a destructive effect on vitamin B (B_1), does not affect G, notably improves the retention of A, and appears to be essential if any C is to be retained. The preservative protects C through cooking as well as drying and storage. The fruits that are regularly sulphured were found to be relatively poor sources of B but are among the richest sources of A and C.

The minimum amount of sulphur dioxide necessary to preserve C was found to be about 500 p.p.m. This is of interest in reference to the observations of Nichols and Reed as to color deterioration, and to those of Joslyn, Marsh, and Morgan,²⁶ who found a simultaneous loss of vitamin C and darkening of color in orange juice.

In press reports²⁷ relating to the work of Balls and Hale of the Bureau of Chemistry and Soils, Washington, D. C., pineapple juice, cysteine, and glutathione have recently been suggested as substitutes for sulphur dioxide in fruit drying. Since these reports were made time has not permitted a careful study of the possibility of using these substitutes in the drying of apricots, peaches, and pears, which apparently had not been tried. Preliminary trials observed by the writer have been rather disappointing and it appears doubtful whether the substitutes will prove adequate.

Until such time as adequate substitutes be found it may well be asked whether the existing regulations pertaining to sulphur dioxide should not be revised. In various foreign countries the tolerances for sulphur dioxide in dried fruits range from 0 to 2,500 p.p.m. Some countries set no limit. In the United States the federal government has no defined limit, but several states have restrictive tolerances or permit none. The maintenance of some of the existing tolerances or the setting up of new restrictions that would not permit the retention of satisfactory color in cut dried fruits would appear to lead toward exclusion of these foods from the diet. In view of their excellent nutritive values, their low relative cost, the seemingly well established harmlessness of the preservative, and the protection it affords against infective agents and vitamin losses, it would seem that uniform and liberal regulations regarding its use would be desirable.

The American Red Cross

Roll Call from Armistice Day to Thanksgiving

Practical Application of School Health Principles*

HAROLD H. MITCHELL, M.D., F.A.P.H.A. (*Life Member*)
School Medical Adviser, Freeport, N. Y.

THE School Health Research of the American Child Health Association has developed certain principles of procedure as conducive to more efficiency in school health programs. These principles have been thoroughly discussed in the Fifth Monograph of the School Health Research Series¹ and in the New York City study, *Physical Defects—The Pathway to Correction*² which was financed by the Metropolitan Life Insurance Company.

I have had an opportunity during the past year to experiment with the practical application of these principles in a school system that is fairly typical of many well managed schools. I was the only school physician and had the assistance of 1 nurse in a system of about 2,000 elementary school children and 1,500 junior and senior high school pupils. I shall discuss the way we applied some of these principles to the health program in our 5 elementary schools. While our efforts were divided with the demands for service and health education in the high school, our experience in the elementary schools offers the most direct application of the principles which came from the research.

We find in the monograph, *An Evaluation of School Health Procedures*,

that certain activities characterized as indicating team work between the nurse and teacher actually produced results. That is, in schools where there was a good nurse-teacher rapport, there we found the best results in the children. Obviously this is a sensible principle but research evidence of its importance leads us to extra efforts to apply it.

We have found in Freeport that nurse-teacher rapport can be developed if the nurse responds *thoroughly* to all requests of the teacher for advice, examinations, and follow-up of her children. When the teacher says she thinks Johnny may have some trouble with his eyes which handicaps him in his school work, an examination is made as promptly as possible, the report is made to the teacher, the observations of the teacher are noted for advising the parents, and the follow-up is consistently reported *back* to the teacher.

I am convinced a large part of the trouble with obtaining the teacher's interest is the failure to take seriously enough such observations as the teacher supposes are significant. Teachers too often feel that their observations have no significance to the nurse and physician, or that they are not sufficiently encouraged to propose further problems. Therefore, we consider almost no work has preference over a thorough investigation and follow-through of every problem proposed by teachers.

Considerable ground work along this

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

line had fortunately preceded me in Freeport. Miss Derrick, our school nurse, had been shrewd enough to recognize that she could accomplish little in follow-up without the fullest teacher coöperation. She had discovered that the annual accumulation of records of physical defects for follow-up were overwhelming if she attempted thorough follow-up upon all of them. The sick child who failed to obtain medical attention, the toothaches, the tonsillitis, acute cervical adenitis, and all the neglected cases referred by teachers were obviously children deserving precedence in her follow-up program. She served the teachers and the teachers responded to her efforts. She soon discovered that her interest in the teachers' questions resulted in further consultations by teachers and reference of more children with neglected health conditions. She realized that the numerous tonsil defects listed by the school physician were not all urgently in need of medical care, and not all could obtain treatment, so she focused her follow-up upon the more serious cases of medical neglect referred by the teachers. And yet there were plenty of tonsillectomies. We found this year that 50 per cent of the 5th and 6th grade children have their tonsils out. But her efforts for tonsillectomy were focused on the really serious cases with medical history indications of need for tonsillectomy.

During the past year we have extended this nurse-teacher rapport as well as a doctor-teacher rapport, not by any peculiar personality influence upon the teachers but merely by applying methods that any nurse can apply. We ask the teachers to observe selected children for eye symptoms. We ask for observations of mouth breathing, for a check up and report of which cases go to a dentist, and which cases obtain tonsillectomy, glasses, or other medical care.

These supposed burdens are put upon the teachers with no complaint from them that they have too much to do; nor do we find that the teacher is not interested. Our teachers are burdened with as heavy a load as those anywhere but they are also interested in doing what they can for the neglected child. A question of the teacher about an individual child's behavior in school or about his psychological reactions in study and play invariably arouses her interest as to the possibility that the removal of physical handicaps may accomplish what she would like to do for the child.

While the teacher is not uninterested, a long list of physical defect symbols after the names of her pupils is certain to leave her cold and uncoöperative. We avoid heaping up too many defect findings for the teacher to interest herself in by the manner of the examination.

We test (1) vision on one visit; (2) hearing on another; (3) teeth are examined at another; (4) when a classroom inspection is made for a check-up on skin and pediculosis or contagion, other conditions are noted for the teacher's observation and report; (5) the more obvious cases of malnutrition may be selected for special observation, or we may advise the teacher as to ways in which she can coöperate in the follow-up; (6) on another occasion the child may have his throat, glands, heart, and other parts examined.

These are screening devices, and I shall say more about the examination later; but I would emphasize that a few cases at a time thoroughly discussed with the teacher invariably arouses her interest and brings forth a willingness to observe, report, and otherwise assist in follow-up. Such discussions with the teacher provide ideal opportunities for instructing her in fundamental subject matter for health education.

We are convinced from our experience this year that the principle of rapport among all the school health personnel as presented in the School Health Study and the New York City Study is not only a valuable asset in obtaining the correction of physical defects but is absolutely essential if we are to make our advice to parents regarding the need for medical care reasonably effective. It is essential if the medical examiner is to consider the history and behavior of the child from one who has observed it. It is the only way that we can get the teacher to understand the needs of her pupils. Certainly an understanding by the teacher of the physical defects of her pupils is necessary if she is to build respect for medical attention and if education is to lead toward a wiser use of community medical resources. No doubt many cases of medical neglect result from a lack of understanding of child needs by parents. Not all parents of children in need of medical care can possibly be visited for effective education by the nurse, but with the teacher's help cases can be selected with discrimination so that personal conferences can be arranged whenever an explanation to the parent will be profitable. Continued follow-through is essential for successful follow-up and this can only be attained with the teacher's interest.

A second principle which came out of the school health research which was associated with good results in the children, was the need for a thorough and adequate examination of the children. This is expressed in the New York City report as, "There should be accurate detection of defect cases with economy of effort," and a corollary of this principle is "The home visit should be backed by authority." In other words, before we launch forth the nurse on the expensive and time consuming follow-up of home visits or indeed any conferences with parents, we

should be sure that the record of defect is truly a defect needing attention. The study in New York indicates clearly that the selection of cases for follow-up had not been made on any such accurate basis. Many cases were missed and many cases were wrongly selected for follow-up. I am confident from experience on numerous surveys and contacts with school health services that a similar degree of inaccuracy in the detection of defect cases prevails in most cities offering school medical and nursing service.

Better examinations have been recognized as desirable for a long time, but only recently has it been clear that it was not practical to supply thorough and adequate health examinations for every public school child every year. My experience in Freeport has given me confidence that such tests as were developed by the School Health Research of the American Child Health Association combined with rapid inspections by a physician can be used as screening devices to select a limited number of cases so that more time can be given to the cases most likely to be in need of attention.

We have used a modified Snellen test devised in the School Health Study for testing visual acuity with increased confidence in its practicability and accuracy as a screening device. It can be used by a technician without medical or nurse training. We ask the children about eye symptoms at the time of the testing; observation is made of blepharitis, inflammation of the conjunctiva and sclera, and cases showing any suspicion of symptoms or inflammation are recorded for observation. Cases for observation are listed for the teacher to observe before initiating follow-up. While not all such selections have sufficiently serious symptoms to justify follow-up, the listing of the cases and the resulting conference with the teacher is very effective in training

the teacher to observe her pupils for eye symptoms, and such teacher observations bring about the discovery of many cases with normal visual acuity who suffer eye strain.

A well trained technician selecting visual acuity cases of 20/40ths or worse can be depended upon to give authority for follow-up. However, before we make the home visit, a conference is held with the teacher for two reasons: (1) to enlist her assistance in a check-up as to whether the child gets an examination by his oculist or whether he goes to a clinic; (2) to get ammunition in order that the nurse may talk with the mother about her individual child. Symptoms observed by the teacher as well as knowledge of the child's progress in class work and behavior are always of interest to parents, and a definite account about a particular child makes the advice to seek medical care effective.

In the 4a Audiometer accompanied by the 2a Audiometer we have another screening device suitable for operation by a technician so that the physician can have time to give the kind of examinations that he is trained to give rather than the kind of march-by examinations so common in public school practice. The phonograph records for this instrument, however, should be improved for greater accuracy. There seems reason to expect that the Bell Telephone Laboratories with the help of the research of the School Health Study will make it possible for us to use this instrument so that we may rapidly and accurately select all hard of hearing pupils.

The New York City Study as well as the monograph, *Physical Measures of Growth and Nutrition*,² has clearly demonstrated that physicians cannot make satisfactory selections of undernourished children under the single examination scheme of school examinations. No doubt extreme cases can be

selected, but such cases are on the average considerably less than 5 per cent. The 10, 15, and 20 per cent ordinarily selected are not proper selections and a better selection is necessary if we are to do anything with malnutrition among school children. The ACH index is a suitable preliminary screening device. But before we initiate follow-up, further measurements of the screened cases are needed to obtain the children underweight for 4 skeletal dimensions and also those with small sized musculature and small amounts of adipose tissue in proportion to their body build. By screening we are able to limit the number requiring thorough examinations so that we can use the complete physical measurements and a clinical history. Such examinations give confidence that we have selected the cases most likely to be in need of medical attention for malnutrition.

I have not been able to try out this plan thoroughly in Freeport because we were not prepared to give adequate follow-up for any large number beyond the possible underfed cases that were under severe economic stress due to unemployment. We have not yet succeeded in selling to our school authorities the idea that the employment of a technician is good economy. We were, therefore, limited in the number of cases that could be measured. We had the services of two CWA workers for several months for follow-up under a trained nutrition worker through the efforts of the County Medical Society. This assistance enabled us to check the food selected by the families on relief and to advise on the buying of food to improve diets in the most needy cases. The school children in these families were all measured and thoroughly examined so that special recommendations for supplementary food for the undernourished children were made to the Relief Authorities. This plan of handling unemployment malnutrition

has been consistent with the principle of "Accurate detection of defect cases with an economy of effort." The selection of the cases under economic stress as the cases for whom we could offer effective follow-up enabled us to provide complete measurement and examination with a clinical history before follow-up was initiated.

A symposium last June at the meeting of the American Academy of Pediatrics was unanimous in agreeing on the importance of the clinical history for deciding on the need of tonsillectomy. While as School Medical Adviser I never advise tonsillectomy, I do have a responsibility not to increase the number of unnecessary tonsil operations, and I cannot say that a child is in need of attention for tonsils without a clinical history except in the very few cases with obstruction or extreme infection.

To screen out the cases most likely to need attention we rely heavily on the teacher to obtain a history. Every absence from school requires an excuse. This year we asked the teachers to distinguish sickness absence from other absences on their reports. Next year they will report the kind of sickness suffered by the child. While accurate diagnosis of every absence case may not be attained, frequent absence due to sickness is a clue to initiate an investigation to confirm the character of the illness. Cases with recurrent sore throat, cervical adenitis, and rheumatic fever are selected for confirmation and then are recommended for tonsil attention.

If the case is likely to go readily to the family physician, we suggest to the parents that they seek their own physician's advice. A child from a family who cannot afford a physician gives us an even greater responsibility for selecting only the cases that can truly profit from medical care. This means in most cases selection of the cases needing tonsillectomy. The cost of follow-up

and the cost of medical care supplied by the welfare agencies demands that we select cases with real indications for tonsillectomy and not place this responsibility for selection entirely upon the physician employed by the relief authorities. In many cases this requires observation and reexamination and investigation of the history in the same way as the pediatrician does in his private office. With 50 per cent or more children being operated upon our concern should be for a wise selection of cases recommended for medical attention and not for more tonsillectomy.

Our screening procedure is, first attention to the cases referred by teachers, then to all cases with a tonsil history as shown by the sickness absence reports, and, finally, we search for suspicious cases by rapid throat inspections and refer these for observation and for report from the teacher—giving her specific advice as to what to be on the lookout for.

A third and one of the most important principles came from the New York City study. That is "The available correction facilities should be considered in determining the severity of a selection for follow-up." Of course there is no point in discovering defects year after year if we cannot do anything about them. Only the most intelligent parents respond to a form notice with no other follow-up. Such parents generally obtain sufficient medical care so that school advice is not often needed, except for vision defects. In order that the nurse may be thorough and not be swamped by an excess of cases both serious and not so serious, we consider her follow-up load in selecting the cases for her to follow up.

All follow-up is graded as to the seriousness of the need. This grading is the responsibility of the physician who makes the final decision for follow-up. Our nursing service is adequate for the worst cases and, as we

improve our teacher interest and improve the efficiency of our record keeping and check-up, we can follow up many more cases. We list our cases: first, as urgent, and second, as suitable for advising parents if and when we are able, and third, as suspicious cases for observation and follow-up when definite indications are confirmed as to the need for medical care. When the nurse clears up the urgent cases, she starts on those less urgent: and as we progress we intensify our search for other less apparent needs, working up the cases under observation. This of course requires close team work between the nurse and the physician. The nurse notifies the physician as she clears up the urgent and less urgent cases so that he may have time for a check-up on teacher observations, sickness absences, and such reexaminations as are necessary to discover other conditions deserving follow-up.

The small number of neglected defects from the more intelligent and well-to-do families generally require little time for follow-up because a tactful telephone conversation generally results in prompt reference to the private physician, and no limitations are met as to medical facilities. On the other hand, we are limited as to free service and we must know how many cases our clinics can handle each week if we are to care for our worst cases first.

In Freeport we very early reached our limit in the facilities of the community free dental clinic. We then arranged a system of appointments for extraction and sent the clinic only the worst abscessed teeth cases, and began our campaign for an increase in facili-

ties to meet the need for serious dental infections. I think we have about solved the problem of neglected abscessed teeth.

Likewise we have met a limit in the facilities for free refraction and glasses and must face next year the problem of caring for a larger number unless the unemployment situation improves greatly. A great deal of time and thought is required to keep clear the coordination of our facilities for medical relief with our efforts in finding the children in need of medical care, and with the follow-up load of the nurse.

I have not time for a discussion of live records that do not require a full-time book-keeper. We have made some progress but further experimentation is needed.

Other administrators may apply these principles using other methods, but I am confident no school health program can give reasonably adequate attention to the medically neglected children without an extravagantly large and expensive staff unless they develop nurse-teacher rapport, use screening devices for selecting children so that their physician may give adequate time to clinical considerations, and coordinate the examination findings with the follow-up and medical care facilities.

Experience With Alum Precipitated Toxoid in Virginia and Observations on the Reaction Following Its Use *

G. F. MCGINNES, M.D., DR.P.H., E. L. STEBBINS, M.D.,
AND C. D. HART, M.D., F.A.P.H.A.

State Department of Health, Richmond, Va.

SINCE the introduction of alum precipitated toxoid, numerous workers have reported observations indicating that it is efficacious in the production of active immunity to diphtheria. Experience of most of these observers has shown that over 90 per cent immunity in originally Schick positive individuals may be expected following the use of a single dose of alum precipitated toxoid. A single dose of toxoid has the advantage of subjecting the patient to but a single unpleasant experience and saving time and expense, thus making the universal use of a diphtheria preventive more practical. Since the experience with alum precipitated toxoid is not yet very large, certain questions and possible objections to its use should be considered. First, does a single dose of commercial alum precipitated toxoid in routine use produce a high percentage of immunity to diphtheria? Second, is the immunity produced by alum precipitated toxoid (as measured by the Schick test) durable? Third, are the reactions following the use of alum precipitated toxoid of sufficient severity to limit its use?

Recently a study has been carried

on in Virginia in an attempt to answer these questions. In order to determine the efficacy of alum precipitated toxoid in the routine immunization of children, groups representing both urban and rural populations, white and colored races, and as wide as possible variations in diphtheria experience have been studied. Seventeen hundred and sixty-five Schick positive individuals were given one dose of 0.5 c.c. or 1 c.c. of alum precipitated toxoid of a potency of from 12.5 to 31.5 flocculating units per c.c., and retested 2 months later; 94.4 per cent of these were found to have been rendered Schick negative. A similar group of 347 were treated the same way but not retested until the end of the year; 95.1 per cent of these were Schick negative.

Table I shows the Schick reaction of these two groups of individuals by age groups and color. The difference between the negro and the white population is significant. This would indicate that artificial active immunization of the negro race against diphtheria is slightly more difficult than the immunization of the white race, a fact which we are unable to explain. There is no significant difference in the efficacy of alum precipitated toxoid in the various age groups nor is any sex variation noted. Four hundred and

* Read at a Special Session on Diphtheria Immunization of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 4, 1934.

10-14	446	317	96.9	91.2	76	29	96.1	93.1
15+	58	36	94.8	86.1	35	3	100.0	100.0
Total	1,026	739	96.3	91.9	267	80	97.0	88.8

eighteen of those included in the group re-tested at the end of 2 months had at some time been given some form of diphtheria immunizing treatment, while 1,347 gave no history of any previous immunizing treatment; but no significant difference can be shown in the efficacy of alum precipitated toxoid in these two groups. In brief, our experience is that no matter what the previous treatment, age, sex, or color of a group has been, 1 dose of alum precipitated toxoid renders over 90 per cent of them Schick negative for at least a year.

In order to compare the durability of the immunity produced by alum precipitated toxoid with naturally acquired immunity to diphtheria and with the immunity produced by other diphtheria immunizing agents, a group of 1,636 Schick negative individuals were re-tested at the end of one year. This group is made up of 550 Schick negative individuals who gave no history of previous immunization, 519 who gave a history of previous immunization, 225 originally Schick positive and rendered Schick negative at the end of 2 months by a high potency toxoid furnished by

TABLE II
REVERSION OF SCHICK NEGATIVES IN 1 YEAR

	Positive	Total	Per cent showing reversion
Originally Schick negative— With no history of previous immunization	36	550	6.5
Originally Schick negative— With history of previous immunization	24	519	4.6
Originally Schick positive— Rendered Schick negative by Park's toxoid	10	225	4.4
Originally Schick positive— Rendered Schick negative by alum precipitated toxoid	19	342	5.6
	89	1,636	5.4

Dr. W. H. Park, and 342 originally Schick positive rendered Schick negative at the end of 2 months by alum precipitated toxoid. Reliable information as to the immunizing agent given the 519 Schick negative individuals who gave a history of previous treatment was difficult to obtain but it is known that most of these received toxin-antitoxin.

Table II shows the reversion of these various groups of Schick negatives in one year. The differences in per cent showing reversion are not significant, indicating that the durability of immunity produced by alum precipitated toxoid is not less than that which is produced by natural causes or by other diphtheria immunizing agents.

The potency of the alum precipitated toxoid used in this study varied from 12.5 to 31.3 flocculating units per c.c. and the dosage of toxoid was either 0.5 c.c. or 1 c.c. Eight hundred and fifteen individuals, including both white and colored, were given 0.5 c.c. of a toxoid containing from 12.5 to 17.3 flocculating units per c.c., while 950 were given 1 c.c. of toxoid varying in potency from 12.5 to 31.3 flocculating units per c.c. Though the differences in the immunity produced by the two dosages are not significant, the percentage rendered Schick negative by the larger dose is consistently higher. While this study was being carried on,

we had the opportunity of observing with Dr. W. A. Browne of the Richmond City Health Department, a group of 250 originally Schick positive children who had received one dose of 1 c.c. of alum precipitated toxoid containing 3.5 flocculating units per c.c. Only 69 per cent of this group of originally Schick positive individuals were rendered Schick negative by this low potency toxoid. It seems, therefore, that the optimum potency of alum precipitated toxoid lies somewhere above this level.

As there has been considerable apprehension concerning the reactions following the administration of alum precipitated toxoid, an attempt has been made to determine the severity of reactions, both local and systemic, following its use. A group of 353 individuals mostly of preschool and school age, have been observed following the administration of alum precipitated toxoid. All were originally Schick positive and were given 1 c.c. of toxoid ranging in potency from 18.1 to 29.7 flocculating units per c.c. The temperature of each individual was taken before the administration of toxoid and again at the end of approximately 24 and 48 hours. The history of each individual was taken at the end of 24 and 48 hours and the local and systemic reactions observed and recorded, and

TABLE III

PER CENT OF INDIVIDUALS SHOWING CERTAIN SIGNS AND SYMPTOMS FOLLOWING THE ADMINISTRATION OF ALUM PRECIPITATED TOXOID

Age	Number Observed	Percent showing reaction	Local Reaction Per cent Showing			Systemic Reaction Per cent Showing						
			Red Area	Soreness and Tenderness	Swelling	Malaise or Headache	Nausea	Vomiting	Increase in Temperature			
									10-1.9°	20-2.9°	30-3.9°	40-4.9°
0-9	203	67.5	41.4	17.2	7.4	10.3	3.4	3.0	25.6	7.9	2.0	1.5
10+	150	72.7	51.3	24.7	16.0	15.3	3.3	4.0	32.7	13.3	1.3	2.0
Total	353	69.7	45.6	20.4	11.0	12.5	3.4	3.4	28.6	10.2	1.7	1.7

all individuals having either local or systemic reactions were observed daily until all symptoms had subsided.

It will be noticed that 69.7 per cent showed some reaction either local, systemic, or both, and that the older ages consistently have a higher percentage showing each symptom indicating that their reaction is more marked. A local red area and an increase in temperature are the most common symptoms.

local reaction was considered to be one in which there was a large, red, indurated area with soreness, tenderness, swelling, and local heat. A mild systemic reaction was considered to be one in which there was from 1 to 2 degrees of temperature elevation with no other symptoms, or no temperature elevation with a single mild symptom. A moderate systemic reaction was considered to be one in which there was an elevation of temperature of more than

TABLE IV
OBSERVATION ON THE REACTION FOLLOWING THE
ADMINISTRATION OF 1 DOSE OF 1 C.C. ALUM PRECIPITATED TOXOID

Age	Number Observed	Per cent Showing			
		No Reaction	Local Reaction Only	Systemic Reaction Only	Local and Systemic Reactions
0- 9	203	32.5	23.2	19.2	25.1
10 +	150	27.3	20.7	14.7	37.3
Total	353	30.3	22.1	17.3	30.3

Table IV shows the relative frequency of local and systemic reactions. It is seen in this group that 30.3 per cent showed no reactions, either local or systemic; 22 per cent showed local reaction only; 17 per cent showed systemic reaction only; and 30 per cent showed a combination of local and systemic reactions.

An attempt was made to classify the severity of both local and systemic reactions into classes of mild, moderate, or severe. A mild local reaction was considered to be one in which there was a local red area less than 5 cm. in diameter, with or without slight soreness or tenderness but showing no other local symptoms. A moderate local reaction was considered to be one in which there was a local area of redness with definite soreness and tenderness with or without swelling. A severe

2 degrees and no other symptoms, or two symptoms with less than 2 degrees of temperature. A severe systemic reaction was considered to be one in which there was an elevation of temperature with headache or general malaise and nausea or vomiting.

Table V shows the correlation between the various degrees of local and systemic reactions. Fifteen per cent showed mild, local and systemic reactions, 4 per cent moderate and 0.3 per cent, or one individual, showed severe local and systemic reactions. Eighty-one per cent of the entire group fall into the classification having either no or mild local and systemic reactions and 19 per cent have moderate or severe local and systemic reactions.

Monroe and Volk¹ have reported a study of the reactions following the administration of untreated toxoid and

TABLE V
CORRELATION BETWEEN SYSTEMIC AND LOCAL REACTIONS
FOLLOWING 1 DOSE OF 1 C.C. OF ALUM PRECIPITATED TOXOID

Local Reactions	Systemic Reactions									
	None		Mild		Moderate		Severe		Total	
	No.	%	No.	%	No.	%	No.	%	No.	%
None	107	30.3	59	16.7	2	0.6	0	0.0	168	47.6
Mild	67	19.0	53	15.0	14	4.0	4	1.1	138	39.1
Moderate	10	2.8	17	4.8	14	4.0	4	1.1	45	12.7
Severe	0	0.0	1	0.3	0	0.0	1	0.3	2	0.6
Total	184	52.1	130	36.8	30	8.5	9	2.5	353	100.0

toxoid to which 0.2 per cent alum was added. In so far as our observations can be compared with theirs, there does not seem to be a marked difference in the reactions following alum precipitated toxoid and untreated toxoid.

In order to compare more clearly the reactions following the administration of alum precipitated toxoid and untreated toxoid, a parallel series of observations were made on 93 originally Schick positive individuals in which one individual was given 1 c.c. of alum precipitated toxoid and the next 1 c.c. of untreated toxoid. These two groups of individuals are entirely comparable in age and sex. The temperature was

taken on each individual before the injection of the toxoid and at the end of 24 and 48 hours afterward. Histories were taken and observations made daily until all symptoms subsided.

Table VI gives a comparison of the per cent of individuals showing certain signs and symptoms following the administration of untreated toxoid and alum precipitated toxoid. No significant difference in the two groups is seen in the per cent showing any reaction. The factors making up the local reactions run almost parallel for the two groups. The per cent showing malaise or headache is high in the group receiving untreated toxoid but the in-

TABLE VI
PER CENT OF INDIVIDUALS SHOWING CERTAIN SIGNS AND SYMPTOMS
FOLLOWING THE ADMINISTRATION OF UNTREATED TOXOID AND
ALUM PRECIPITATED TOXOID IN A PARALLEL SERIES

Toxoid Administered	Number Observed	Per cent showing reaction	Local Reaction Per cent Showing			Systemic Reaction Per cent Showing						
			Red Area	Soreness and Tenderness	Swelling	Malaise or Headache	Nausea	Vomiting	Increase in Temperature			
									1°-1.9°	2°-2.9°	3°-3.9°	4°-4.9°
Alum Precipitated	50	68.0	52.0	30.0	6.0	2.0	0.0	0.0	30.0	8.0	2.0	0.0
Untreated	43	67.4	39.5	27.9	9.3	14.0	2.3	0.0	27.9	2.3	2.3	0.0

definiteness of this symptom and the small number observed make this difference of little significance. The temperature elevations are almost parallel in the two groups.

ing alum precipitated toxoid are in any way different from the reactions following untreated toxoid.

More than 3,000 children were given a single dose of 0.5 c.c. or 1 c.c. of

TABLE VII
OBSERVATION ON THE REACTION FOLLOWING THE
ADMINISTRATION OF UNTREATED TOXOID AND
ALUM PRECIPITATED TOXOID IN A PARALLEL SERIES

Toxoid Administered	Number Observed	Per cent Showing Reaction	Local Reaction Per cent Showing				Systemic Reaction Per cent Showing			
			No Reaction	Mild	Moderate	Severe	No Reaction	Mild	Moderate	Severe
Alum Precipitated	50	68.0	52.0	40.0	8.0	0.0	58.0	38.0	4.0	0.0
Untreated	43	67.4	51.2	39.5	9.3	0.0	58.1	37.2	2.3	2.3

Table VII shows the comparison of the local and systemic reactions observed in these two groups, according to the classification of mild, moderate, and severe. This comparison shows a great similarity in the two groups, both in local and systemic reactions.

Table VIII shows the correlation between local and systemic reactions in the two groups. The two groups are indistinguishable in the per cent showing no reaction, local or systemic only, or local and systemic combined. There is no evidence that the reactions follow-

alum precipitated toxoid during this study and only one individual developed an abscess at the site of injection. This occurred in a Schick positive white, female, 11 years of age, who gave a history of previous immunizing treatment with toxin-antitoxin. There was a severe local reaction following the administration of the toxoid with abscess formation on the 5th day. The abscess drained spontaneously and healed rapidly.

Recently in Virginia, a high percentage of abscesses were found follow-

TABLE VIII
OBSERVATION ON THE REACTION FOLLOWING THE
ADMINISTRATION OF UNTREATED TOXOID AND
ALUM PRECIPITATED TOXOID IN A PARALLEL SERIES

Toxoid Administered	Number Observed	Per cent Showing			
		No Reaction	Local Reaction Only	Systemic Reaction Only	Local and Systemic Reactions
Alum Precipitated	50	32.0	26.0	16.0	26.0
Untreated	43	32.6	25.6	18.6	23.2

ing the use of a single lot of alum precipitated toxoid. All abscesses were confined to those having received toxoid bearing this particular lot number. In a group of 112 individuals receiving 1 c.c. of alum precipitated toxoid bearing this lot number, 12 had abscesses which required surgical attention. Material was cultured from each one of these abscesses and in all instances was found to be sterile. This occurrence was reported to the National Institute of Health for investigation.

Experience with the use of alum precipitated toxoid in Virginia would seem to indicate that abscess formation need not necessarily be expected following its use.

CONCLUSIONS

One dose of alum precipitated toxoid

of a potency of 12.5 flocculating units per c.c. or greater produces over 90 per cent immunity in known Schick positive individuals.

There is not a significantly greater reversion to the Schick positive state in individuals rendered Schick negative by alum precipitated toxoid than in Schick negative individuals rendered Schick negative by natural causes or following other diphtheria immunizing agents.

Reactions following the administration of alum precipitated toxoid are not of sufficient severity to limit its use, nor are these reactions of greater severity than those following the administration of untreated toxoid.

Medical Slang

WORSE than medical jargon is medical slang. The best type of medical writing is that which appears in the case report. The use of the word "gut" for intestine or the plural of the word for the other contents of the abdominal cavity may be considered a medical affectation quite as bad as "the acute abdomen." When the surgeon says he did a "chronic appendix," when the gynecologist speaks of "an abdominal woman," when the dermatologist "puts the patient on iodides," or when the internist says the patient "runs a swinging temperature," they are speaking medical slang. The gynecologist would hesitate to speak of doing a Caesar when he performs a caesarean operation.

These are some of the specific ex-

amples cited by Hurter, and there are many more in *The Art and Practice of Medical Writing*.

In the field of medical science, many men have gained note by their ability to express themselves in good English succinctly, rhythmically and accurately. The opportunity is available, for everyone who cares to take the trouble and the time, to perform competently in the field of medical letters. Experts assert that there are hardly a hundred competent medical writers in our country today; some authorities insist that there are hardly more than 10 or 12. In the field of preparation for sound literary expression, particularly, preliminary education to medical training seems to be failing miserably.—Editorial, *J.A.M.A.*, Sept. 15, 1934, p. 842.

Health Education in Germany*

BRUNO GEBHARD, M.D.

Deutsches Hygiene Museum, Dresden, Germany

IT is a great honor for me to speak to you about Health Education in Germany. If there is anything in which you are specially interested, I hope that I may have an opportunity to answer questions afterwards.

I have no special personal philosophy regarding health; a man is healthy who can perform all the duties required by his nation, his profession, and his family. It is not enough only to be healthy. Those persons living only for their health, as they say (I call them health-hypochondriacs) have not a great interest for the health educator. Such persons have "eine falsche Gesundheit" . . . they do not eat to be satisfied, but rather to obtain the proper amount of calories and vitamins.

One question for a health worker, who does his work on a scientific basis is the following: What can be done by education? What health factors are determined by heredity, and what influence can social conditions have? If health workers would obtain success they must, of course, give consideration to such factors, which I will not take time to discuss here.

About Germany—There is one great difference between this country and my home. Germany is an old country, nearly 2,000 years old in its history. There are many different native racial tribes—Prussian and Bavarian, Silesian,

and people from the Rhine, have different hereditary backgrounds. The greatest difference is in regard to the population. The area of the States is 18 times greater than that of Germany. It is better to say that the State of Texas is a little larger than all of Germany, but in Germany there are 66 million people, as compared with 2 million in Texas.

WHAT IS THE AIM OF HEALTH EDUCATION IN GERMANY?

I think there is a new idea of health education since the Great War in those countries which have suffered much through the war and due to its consequences. Millions of people have learned, and have been led to appreciate the value of life, and the value of health.

Health Education in Germany seeks to teach the individual to value life, not to throw it away—to regard it as a trust. To us the aim of education for health is: the healthy man, the man physically and mentally well balanced, who knows and perceives what is beneficial for him, who recognizes health as a most precious gift of life, always worthy to be striven for.

If there is any right of health for every citizen there is also a duty for each to strive for vigorous health. We say in Germany, "Der einzelne ist nichts; die Volksgemeinschaft ist alles." To be healthy is nothing—to maintain yourself to work for the national welfare, that is everything.

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

The persons in Germany doing the work of health education are, first, the health officers. There are health officers of the State called "Kreisarzt," and health officers of great towns, "Stadt-artz." Some rural districts have also county health officers for preventive medicine and health work. The Reich recently adoted a new law "bringing all health work under one sole direction." Now there must be in each town and county a state health officer; formerly it could be, but it did not have to be. In the Reichministerium of Interior there is a special department for health service, including health education.

The second chief-worker in health education is the teacher. I think in many cases the teachers are better trained for health education than the doctors. In Germany the work in health education in the school is done by the teachers. There is another method in England by which the health officer lectures in the school. I do not know how it is in this country.

We should not forget the parents. More important than knowledge about health and hygiene is the education for healthy habits, and that must be done by the parents in the first 5 years of childhood. We have a German proverb, which is, "Was Hanschen nicht lernt, lernt Hans nimmermehr." "What little Jackie does not learn—adult Jack would never learn." We have so-called "Mutterschulen" and there are special evening classes where the fathers come also. Home nursing not only requires a kind heart, but also a clever hand and a clear head. People are seldom born with these qualities, but with proper instruction they can easily be acquired by most men and women.

We have in Germany a law which requires the registration of tuberculosis and venereal diseases. If any person is ill of one of these, the doctor must give the patient's name to the health officer who gives the sufferer and his

family special instructions about the sickness, how to cure it, and so forth. Our new state laws provide a great opportunity for personal work in health education, especially in eugenics—not to forget the Health Insurance Institutions and many private organizations dealing with alcoholism, tuberculosis, and venereal diseases. There are also special institutions in Germany, "Die Berufs Schule." These are of great importance in our health education work. Boys and girls from 14 to 17 have to learn many things about health; for example, the instruction given to girls, how to nurse the babies. The German Arbeitsdienst, similar to your CWA, is one of the best opportunities for adult education between 18 and 25. They are given gymnasium each morning, swimming, hiking, and so forth, with instruction in first aid. In Germany we have such organizations for girls also, but they are voluntary.

The methods of Health Education are, I think, quite the same in Germany as in your country. More and more we prefer intensive work between individual and individual. We have also extensive health campaigns—but we do not believe much in their success. You can give great figures of how many millions of pamphlets you distributed and make a good impression on laymen, and from time to time it is valuable to have big exhibits. I must tell you a little story. We had a great hygiene exhibit in Dresden, 1930–1931. Several days we looked around with the well known Mr. and Mrs. Routzahn. One day he asked: "Would it not be better to have a smaller exhibition than a big one?" "Yes," I said, "but we had 10 small ones and no Mr. Routzahn came from America to see them, but now we have the big one and Mr. Routzahn has come to Germany."

The means of Health Education are so many that it is not possible to speak now about them. The best is the

spoken word—from individual to individual. Our medical practitioners have almost forgotten it. An old medical sage says: "You can cure a man by remedy and by word." I think there must be more educational work by the medical practitioners. You cannot help a man alone by giving him a prescription, or doing an operation.

The printed word, pamphlets, books—We need them but they have not so great an influence. Better are pictures, lantern slides, films. We prefer lantern slides for instruction, and films for health propaganda.

THE WORK OF THE DEUTSCHES HYGIENE MUSEUM

Our Museum was founded in 1912. The year before the first International Hygiene Exhibition was opened at Dresden. This exhibition was the pioneer in giving hygienic instructions to the masses of the people. In 4 months more than 5½ million visitors saw the exhibition. The greatest success was the department, *Der Mensch* (Man). Since then the Museum has steadily developed into a central institution for public health. The new home of the Deutsches Hygiene Museum was opened in the year 1930. Its fundamental aim is laid down in a memorial pamphlet by the founder, Dr. Lingner, who said:

The Deutsches Hygiene Museum is to be a place of instruction for all, where everyone may acquire instruction necessary for healthy life. The exhibits are to be arranged in such manner that laypeople may understand them with the help of simple explanations. The construction of those models is a highly scientific work and a specialty of the scientific department.

The focus of the Museum is the collection, *Der Mensch*, with a separate room for the so-called "Transparent Man." It is really a wonderful model, made of a kind of celluloid, and the inner organs such as the heart, lungs,

brain, and so on are lighted up automatically one after the other. The twenty museum-halls housed in two different floors, cover nearly 6,000 sq. m., or 7,500 sq. yds. The collections of the Museum deal with biological-hygienic instruction, the anatomical and physiological foundations of physical exercise, the care of mother and child. There is a special division for eugenics and for the problem of right nourishment. Industrial hygiene and the protection of workers have their places. Quite modern is the room *Health and Sickness*. The problem of modern biological science, as constitution, disposition, and the influence of surroundings upon health are here demonstrated in a most instructive manner.

This is followed by the department of such infectious and contagious diseases as tuberculosis and venereal diseases. A special room deals with the problem of cancer. Two combined historical and ethnographical groups show the hygienic and non-hygienic life in classical times and in the middle ages, and also those things which are interesting as hygienic usages in the life of natives such as the negroes in Africa, the Indians, the Chinese people and so on. A special room is reserved for temporary exhibits, which are changed every month.

There are not only these exhibition rooms; there is also a school for expectant mothers, a cookery school especially for special diets; there are rooms for classes in first aid, and for evening classes; there is a gymnastic room, and also a library with a large collection of 3,000 illustrated posters from all parts of the world.

There is one unique characteristic of the work of the Deutsches Hygiene Museum. All the exhibits are made in our own special workshops, whether pictures, placards, lantern-slides, models, anatomical preparations (after Prof. Spalteholz') wax models. There are new models of celluloid, unbreakable,

not affected by heat or cold, much lighter than wax, and cheaper by one-third.

Another aspect of the Museum's work is of great interest for public health workers. After the war the Museum sent out several itinerant exhibitions. In 1919-1920 people were badly undernourished, and in consequence many died of tuberculosis. The Museum started a special exhibition to teach people how to avoid tuberculosis, and advised them to consult a doctor in good time. It was also necessary to have an exhibition enlightening people on venereal diseases. Since then there have been shown many traveling exhibitions in most towns and villages of the Reich. They are called: "Fight Cancer," "Right Nourishment," "Healthy Women—Healthy Nation," and so on.

There is also an automobile exhibit with a special tent, serving as an exhibition hall wherever the car stops. Dr. W. W. Peter calls this automobile the "Healthmobile." It travels through the rural districts of Germany, staying 2 to 3 days in each place to show the people of the district how to live healthily. Twenty million visitors have seen our exhibits in Germany. The traveling exhibits are also taken abroad. The Museum has shown its exhibits in many towns of Switzerland, Austria, Czechoslovakia, in Sweden, Norway, Hungary.

The appreciation which the Museum's work has met, is further proved by several requests to organize new museums or to lend certain important exhibits to different countries. Many

such requests were granted as in the case of the museum at Klausenburg (Roumania). Also the Egyptian Government commissioned the Museum to organize a museum in Cairo. It is the same with the Yugoslavian Government: we organized two museums there at Belgrade, and one at Agram. The Hygiene-Section of the League of Nations requested the Museum to arrange material for medical education at Warsaw, Moscow, and Charkow. It may be known to you that there are many models of the Deutsches Hygiene Museum in the scientific halls of the Century of Progress Exposition in Chicago.

Nearly 700,000 lantern slides, 350,000 illustrated posters, and many thousand casts and models from the Museum are used throughout the world. The Lantern Slide Service alone has more than 100 series, and each has from 50 to 60 slides concerning all branches of public health. They are employed in schools and for special lectures. One can hire or buy them, and they can be used in any country no matter what its language.

These are some of the services which it has been the privilege of the Deutsches Hygiene Museum to perform in its homeland and abroad. The institution is a tangible evidence of the vision and faith of its founder in the efficacy of visual methods in health teaching. The fight against sickness and unhygienic conditions knows no territorial boundaries. In this work the Deutsches Hygiene Museum is glad to be associated with health educators in America and in other parts of the world.

Health Problems Connected with the Ethylene Treatment of Fruits*

E. M. CHACE

*Laboratory of Fruit and Vegetable Chemistry, Bureau of Chemistry and Soils,
U. S. Department of Agriculture, Los Angeles, Calif.*

CONSUMERS are prone to judge the quality of fruits by the appearance. Nicely colored oranges, bananas or peaches which are attractive to the eye will sell better than an equal or even better quality of the same fruits not so well colored.

For ages therefore fruit shippers have endeavored to improve the color of their wares by polishing, waxing, wrapping in colored paper, holding in warm humid atmospheres and other devices. However, nature affords many examples where color is not correlated with quality or even maturity. For instance, the California Valencia orange is better colored in January or February before it is mature than it is at the height of its maturity in August, for as soon as hot weather sets in the stem and blossom ends of this fruit begin to turn green. If the consumer will pay more for well colored fruit the growers and shippers of that fruit will do their utmost to secure the premium paid for appearance. While undoubtedly the ethylene treatment is used for this very purpose, the events leading up to its discovery come wholly from another line of endeavor; namely, attempts to avoid freezing of the fruit during packing and shipping.

In the Tulare County, Calif., orange district in the early days of orange shipments kerosene stoves were used in the packing sheds, and in a few cases, in the cars in order to avoid danger of frost injury. One or two fires in transit, and the railroads put a stop to their use in cars. Shippers state that at first they had no other purpose than to keep the fruit warm, but eventually noticed that fruit heated in this way developed a better color than that packed without heating. Kerosene stoves were used solely for the reason that they were available and afforded the cheapest source of heat. Some enterprising but unfortunate individual built a heating plant using steam in place of the cumbersome kerosene stoves, and discovered to his dismay that he could get no better color in this way than if the fruit were not heated. Very soon the use of kerosene stoves became universal in citrus packing houses. Gas and the exhaust from automobiles and motorcycles were also used. In 1912 Sievers and True, Bureau of Plant Industry *Bulletin* 232, U. S. Department of Agriculture, proved that the combustion gases were responsible for the increase in color of fruit exposed to them.

Various methods were employed to apply these combustion gases, blue flame burners were placed in the coloring rooms surrounded by the oranges in

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

boxes just as they had come from the field. The stoves were placed in basements under the coloring rooms, the gases ascending through the latticed floors, and finally the stoves were placed in cement houses outside the packing houses and the fumes circulated by means of fans and conduits to the coloring rooms. The latter method was an improvement over keeping the stoves in the rooms where with the best of attention the fruit was too often covered with soot from smoky burners. An idea prevailed at this time that the more evil smelling the atmosphere in the coloring rooms the quicker the coloring would take place. The atmospheres were often so acrid and tear compelling that the rooms had to be ventilated for some time before the workmen could enter without being subject to headache and other discomforts.

A later development was the installation in Tulare County of a set-up for making carbon monoxide, by injecting steam into incandescent coke. Not only was this a serious menace to the workmen but was a failure as a coloring agent. Up to this time the coloring of fruit was more or less haphazard. The results were never certain, the fire risk was high and the care of the stoves troublesome.

We began our investigations of the coloring problem in 1918 by ascertaining the constituents in the atmospheres of the coloring rooms. Owing to the variety of conditions encountered great difficulty was experienced in drawing conclusions from the data obtained. The coloring efficiency was not correlated with carbon dioxide or carbon monoxide, unsaturated hydrocarbons or with any other constituent or factor which we could recognize. Finally by separating the different groups of constituents from the combustion gases of the kerosene stoves it was discovered that the unsaturated compounds were those having the property of improving the color of the

fruit. As ethylene and acetylene were the unsaturated compounds present in greatest quantity, they were given first trial. Apparently both gave satisfactory results but further investigation proved that purified acetylene was not effective. In all probability traces of ethylene in the acetylene had accelerated the coloring. Fortunately ethylene was being produced commercially, having been used during the war in the manufacture of poison gas. It was found that ethylene in dilutions as high as 1 part in 2,000,000 would noticeably accelerate the coloring of black green lemons. For commercial practice on citrus fruits, 1 part in 5,000 to 10,000 parts of air seemed to give most satisfactory results. That high dilutions of the gas were efficient was also fortunate for even at the maximum strength recommended, 1 part to 1,000, 30 times that amount would have to be used before an explosive mixture would be obtained. In 1923 Dr. F. E. Denny, who had been working in our laboratory on this investigation secured a public service patent covering the method.

Commercially the gas is dispensed in cylinders containing from 25 to 30 lb. (about 300 cu. ft.) under pressures of 1800 lb. per sq. in. The method of operating is to place the fruit in packing boxes, stack the boxes in a reasonably gas-tight room in such a way that the circulation of air about them will not be hindered. The gas is then run into the room through a flow gauge or other measuring device until the proper proportion is reached. The rooms are thoroughly ventilated and recharged every 6 to 12 hours, depending on weather conditions. Where continuous ventilation is used the gas is permitted to "trickle" into the air current. During hot weather this system has the advantage of keeping the temperature in the treating rooms within a reasonable range.

Ordinarily citrus fruit will color in

from 2 to 5 days under this treatment and will soften sufficiently for satisfactory packing.

The treatment of other fruits is essentially the same. With pears and the Japanese persimmon 1 part of gas to 1,000 of air is used although 1 in 5,000 would probably work as well. In 4 to 6 days pears soften, become yellow and are in excellent shape for canning. With pears the chief object of the treatment is to save sorting. Left to themselves, pears would require from 10 days to 2 weeks to soften and would do so unevenly. This uneven maturity could be taken care of by sorting, but at extra expense and with some loss in the grade, for at each sorting a few of the pears are sure to be bruised.

In the case of persimmons, from 48 to 96 hours will do the trick, softening them, coloring them and removing the astringency better than if they are kept in storage until soft.

Our personal experience with tomatoes has not shown a profitable use for ethylene. It has been reported as used with satisfaction by some shippers and jobbers. We have also had reports on its successful application to bananas.

The latest development, one upon which we are now working, is the use of the gas for removing the hulls from walnuts. In order to secure the best quality the walnuts in some districts of California should be harvested as early as possible. If they are harvested early, however, there will be a considerable percentage of "sticktight" nuts—in other words those from which it is almost impossible to remove the hull. Treatment with ethylene causes the hulls to become friable so that they are readily removed by the various hulling devices.

The changes produced by ethylene are solely those which would have been brought about by nature in a somewhat longer time and less uniformly. Whether this hastening of the natural

reactions is due to activation of the enzymes contained in the fruit or whether it is caused by a changed permeability of the tissue which allows the enzymes to come in contact with and change the natural constituents, is difficult of proof. We have never encountered a change which is not a natural one. The process is often called a coloring process, which in one sense is a misnomer. It does not add color but destroys chlorophyll by the usual processes of nature and leaves the natural color of the fruit in its place. This is illustrated by the changes in both citrus fruits and persimmons. No matter how long grapefruit or lemons are treated with ethylene they will not assume an orange color. When the chlorophyll is destroyed through the indirect action of the gas only the natural color of the fruit remains. Oranges which are harvested before maturity, when treated rarely develop a good orange color but are more of a lemon yellow than orange. Persimmons gathered too early will not yield a satisfactory color on processing, but will be dull reddish brown instead of red.

Contrary to popular belief, neither the sugar nor acid of citrus fruit is changed by the treatment. It has been a common practice in some packing houses to set aside or treat fruit that does not reach the maturity standard required by law, in the belief that in a few days it will gain in sugar or lose in acid enough to pass the test. Sometimes such changes are supposedly brought about by ethylene treatment or by storing. In such cases, however, irregular sampling is the cause of the apparent change. No matter how many adverse results have been secured the packer will base his conclusions on one favorable test, when a few more tests would show him the fruit as a whole had not changed.

In some fruits where nature has provided material from which sugars are

produced by natural processes, such changes will take place during the treatment. Bartlett pears and bananas contain starch which even after the fruit is picked will change into sugar. Ethylene will bring about this change in pears in 4 to 6 days, whereas if left to stand it would take from 10 days to 2 weeks to accomplish the same result. The treated pears will be uniform in color and texture, whereas the untreated will not.

In the case of the Japanese persimmon the changes in the tannin compounds are likewise much more uniform in the treated fruit. The astringency will entirely disappear during treatment with no traces left, as is common when the fruit matures naturally.

If our conclusions are correct and only the natural reactions take place on treatment, there is little to be said on the health problems connected with the process.

However, the question of the hazard to health may be considered from 2 points: (1) the dangers to the workers in the fruit packing plants or canneries; (2) the consumers' risk in eating the treated material. We have never noted the least inconvenience among our own or other workers from breathing the usual dilutions of the gas employed. It is well known that ethylene is an anesthetic and that ethylene-air mixtures are explosive. As an anesthetic it is mixed with oxygen in ratio of 4 parts of gas to 1 of oxygen. Explosive mixtures must contain from 3 to 25 per cent of ethylene in air, so that a mixture 30 times as strong as that recommended would have to be used before the danger point for explosion would be reached, and 800 times before there would be danger of anesthesia. The insurance and indemnity companies have gone into the matter thoroughly and permit the use of the process in insured buildings under certain restrictions.

Under the second heading it could

be conceived that danger might come from impurities in the gas absorbed by the fruit and carried to the consumer in this way. Impurities common to ethylene amount to about 2 per cent, 75 per cent being ethane, a saturated hydrocarbon gas not so active chemically as ethylene. Traces of carbon dioxide, propane, acetylene, and acetone also occur. All are probably quite harmless in the dilutions in which they occur. Acetone and acetylene are present in the treating room atmosphere in the proportion of 1 part per 1,000,000. It would appear therefore that the hazard from this source is negligible. It is within the realm of possibility that the reactions caused by the gas within the fruit might form injurious compounds. We have not discovered any reactions caused by the treatment that would not take place naturally in a longer time.

Another phase of the question which must be considered is the possible effect of ethylene on the vitamin C potency of the juices made from fruit treated by the process. A thorough investigation of this question has been made by experts in the Department of Agriculture.* Tests were made on fruit picked at the same time from the same tree, part of which was allowed to stand at room temperature, and part treated with ethylene immediately after picking. The fruit was picked from all sides of the tree so as to obtain specimens of approximately the same size and maturity. The two lots were analyzed on the same day, being titrated with a suitable indicator to determine the reducing value of the juice and thus give an index of vitamin C content. The following results were obtained:

Control sample, immediately after picking 7.11 ± 0.98

Control sample, after holding at room temperature 7.19 ± 0.94

Treated sample $7.03 \pm .102$

These data indicate no significant

* Unpublished data, this Bureau.

difference between the reducing values of the juice from oranges treated with ethylene and from similar fruit not treated. The indications are, therefore, that the vitamin C content of the fruit is not affected by the ethylene treatment.

The concealment of inferiority by coloring is more a question of fraud than of health. With few exceptions fruit harvested before it is commercially mature will not color satisfactorily. We have had complaints from those interested in child feeding that the fully colored oranges they were getting were too sour and caused digestive disturbances in children. These complaints are usually received at the time when it is necessary to switch from the summer crop to the winter crop or *vice versa*. The crop which is closing is thoroughly matured fruit low in acid. The new crop naturally is higher in acid even if

it is commercially mature. There is no way to avoid the change unless canned or frozen juice can be substituted for the fresh. This can be done now with the assurance that the full vitamin C content of the juice is preserved and that a satisfactory flavor will be found. Commercial maturity is defined by state laws in both Florida and California. The provisions are liberal and the fruit which will pass the standards is not satisfactory to everyone. On the other hand, not all fruit which becomes fully colored on the tree would be satisfactory to everyone.

In conclusion we feel that the ethylene process has deservedly found a place in the preparation of fruit for the market, that it is harmless, and that with proper state and federal regulation little if any fraud can be perpetrated through it.

Buy Christmas Seals

Help Fight Tuberculosis

"Little Red" Cottage

THE Christmas Seal this year commemorates the 50th anniversary of the beginning of modern sanatorium treatment in the United States by the late Dr. Edward Livingston Trudeau at Saranac Lake, New York, in February, 1885. The one room cottage the seal depicts became the nucleus of the sanatorium movement in this country. Today there are 659 sanatoria containing a total of 86,917 beds. The cottage, called the "Little Red" because of its color, is preserved at the institution founded by Dr. Trudeau, which today bears his name.

Pleo-Antigenicity of Proteus X19^{*}

HENRY WELCH, PH.D., FRIEND LEE MICKLE, F.A.P.H.A.,
and EARLE K. BORMAN

*Research Microbiologist, Director, and Assistant Director, Bureau of Laboratories,
State Department of Health, Hartford, Conn.*

IN a previous study Welch and Poole¹ reported the finding of a pleo-antigenic variant occurring spontaneously in a stock strain of Proteus X19. It was demonstrated that both the spontaneous variant and an artificially induced variant would agglutinate in antisera for members of the Shigella, Eberthella and Salmonella groups of organisms whereas the parent Proteus X19 strain was inagglutinable in such sera. Further study indicated the phenomenon was not due to acquisition of new antigenic components by these variants but that the parent Proteus X19 strain had in its makeup similar agglutinogens although not demonstrable by direct agglutination. The presence of these agglutinogens could be demonstrated, however, by the production of the corresponding heterologous agglutinins in sera of animals inoculated with the parent strain. In this connection, Mackenzie and Fitzgerald² have demonstrated that antigenic components not demonstrable in the original parent culture may appear in variants of organisms of the Salmonella and Shigella groups.

Because of the wide use of Proteus strains by diagnostic laboratories in the Weil-Felix reaction it seemed of practical importance to study in a similar

manner strains † obtained from various sections of the United States and Canada in an attempt to determine whether other strains in use had similar characteristics to the one previously reported. Nineteen of these strains were being used diagnostically; 5 were labelled as variants when received. The morphology, biochemistry and serology of 22 strains from this country and 2 from Canada have been studied and are reported on in this paper.

MORPHOLOGY

Microscopic—Each strain was studied microscopically using direct smears from the original agar slant culture. There were marked variations in morphology. In many cultures Gram-positive staining organisms were present although Gram-negative short bacilli predominated. In 17 of the 24 cultures studied long filamentous forms were evident ranging from approximately 2 per cent to 90 per cent of the organisms in each microscopic field.

† Strains designated by names of states, provinces, National Institute of Health, and New York City are used diagnostically in the Weil-Felix reaction in these official laboratories. The 4 Storrs strains were obtained from the Department of Bacteriology of Connecticut State College. Three of these were known variants originally obtained from Dr. Philip Hadley. The HXX and OXX (Kingsbury) strains were obtained from the Harvard Medical School. Department of Bacteriology and Immunology, with information that these had been received recently from Dr. A. Felix of the Lister Institute. The strain designated Norton was received from the Department of Bacteriology of the Upjohn Company of Kalamazoo, Mich. The authors express their appreciation to all who kindly furnished the cultures for this study.

^{*} Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

TABLE I
BIOCHEMICAL REACTIONS OF 20 PROTRUS X STRAINS

[illegible]

This was particularly true of the National Institute of Health Strain 504 which on receipt showed a majority of interwoven filamentous forms with only a few shorter rods. In most cases where filamentous forms were observed definite Gram-positive granules could be distinguished. Although cultures varied in morphology from short, fat rods to long, narrow, filamentous forms, there was nothing sufficiently clear-cut to separate these strains into groups on a morphological basis.

Macroscopic—The colonial study of all strains was made on eosin-methylene-blue agar for a 72 hour growth period at 37° C. On this medium 15 strains developed a definite metallic sheen similar to that produced by *Escherichia coli*, some strains producing this sheen within 24 hours. Of the 9 strains showing no metallic sheen, 4 were known variants. In most instances at least 2 distinct types of colonies developed, ranging from 1 to 5 mm. in diameter—one usually clear, colorless, raised, glistening, entire and convex; the other opaque, blue to black in color, raised and convex with erose edges. Between these extremes were several gradations in color, size, and morphology.

In an attempt to determine whether there existed in these 24 strains under study variants similar to the one previously reported,¹ more than 150 colonies were fished from eosin-methylene-blue agar plates, and further studies made of the biochemical and morphological characteristics of the resulting strains. In no instance were we able to isolate in this manner directly from the cultures, variants of the type mentioned above.

In broth (pH 7.2) all cultures grew moderately well showing an even turbidity with small amounts of flocculent precipitate in the bottom of each tube in most instances. Hanging-drop preparations were made on 3, 8, and 24 hour broth cultures and, although it

has been demonstrated³ that the 'O' antigenic component is the reacting factor in the Weil-Felix reaction, 17 of the 24 strains studied were found to be motile. The results of the motility studies are given in Table I.

In studying the histories of the 24 strains interesting information was obtained regarding the condition of the cultures from a motility standpoint. On the basis of the source from which the cultures were originally obtained the 24 strains could be divided into 4 groups. In the first group were 3 strains: New York 211, Ontario, and Quebec, all of which, the histories indicate, were originally obtained from Dr. H. Mooser of Mexico City who designated these cultures as "O1." At the present time only one culture (Ontario) is non-motile. In the second group there were 12 strains all of which, according to the accompanying histories, were obtained at various times (1919-1932) from the National Institute of Health. Five of these were non-motile; National Institute 504, Connecticut, New Jersey (2 cultures—both National Institute 18), and Alabama. (In the history obtained with this last strain it was noted that some difficulty had been encountered with this culture and it had been found necessary to fish non-motile colonies after plating it out.) The American Type Collection, Massachusetts X2, Massachusetts X19, Norton 50, California, Ohio, and New York 32,276 strains were all motile. In the history of the latter it was noted "strain 32,276 was received from the National Type Collection in 1932 and was listed in their 1931 catalogue as 3,138-O derived by Weil and Felix from their 3,137-H." In the third group were placed 4 strains for which no history was obtainable, all of which were motile. These were Wisconsin, New York City, Storrs X19, and Michigan. In the fourth group were placed the 5 known variants; 4 of these were motile

* Homologous titers.

(HXK-(Kingsbury), Storrs Rough Mucoid, Storrs Mucoid, and Storrs Smooth), and 1 strain was non-motile, OXK-(Kingsbury) strain.

This portion of the investigation indicates definitely that *Proteus* strains to be used diagnostically in the Weil-Felix reaction must be checked for motility at reasonable intervals if such cultures are to be maintained in the proper and most efficient state. In connection with this our investigation would indicate that diagnostic *Proteus* strains should be carried in stock cultures on media from which the water of condensation has been removed by dehydration since the presence of this water apparently increases the possibility of the development of motile variants from what was originally a non-motile strain.

On Krumwiede's triple sugar medium an acid and gas butt and an acid slant were produced by 20 of the 24 strains. Two strains showed an acid butt without gas and an acid slant, both of which produced gas in small quantities in carbohydrate media. The other 2 strains produced acid and gas butts and alkaline slants.

BIOCHEMICAL REACTIONS

All 24 strains after being tested for purity were inoculated into carbohydrate media (sterilized by filtration) and examined each day for 18 days. The biochemical reactions are given in Table I. In general, except for the known variants, acid and gas were produced in dextrose, sucrose, salicin, maltose, cellobiose, xylose and galactose. Lactose, mannitol, rhamnose, arabinose, raffinose, inositol, dulcitol, sorbitol, adonitol and dextrin were not fermented by most strains. However, 8 cultures produced acid in glycerol. The HXK and OXK strains failed to ferment salicin and maltose. The Storrs Smooth and Storrs Mucoid strains failed to ferment salicin, but did ferment maltose

(one of these, Storrs Smooth, produced acid and gas in arabinose). The New York City* strain, which according to its history had been carried in stock 22 years, showed the greatest amount of variation from the typical *Proteus* fermentation, producing acid and gas in lactose, arabinose, and raffinose. The carbohydrate reactions of this particular strain are similar to the reactions of certain strains of *Escherichia coli*; however, in the serological studies of this strain definite agglutination in high titers were obtained with *Proteus* X sera. Apparently long cultivation on artificial media had brought about these variations from the original type. The American Type Collection strain did not produce gas in carbohydrate media. Most strains were able to grow in Koser's citrate medium. The Voges-Proskauer test was negative with all 24 strains, which gave positive methyl-red tests and reduced nitrates. Six strains failed to produce indol and 16 liquefied gelatin. The reactions in litmus milk ranged from acid to neutral, and 3 cultures, all variants, showed peptonization.

SEROLOGICAL STUDIES

In order to test the serological relationship of the strains under study, 12 rabbits (free from natural agglutinins) were injected every day over a period of 12 days with increasing doses of live organisms. The 12 strains chosen for preparation of sera were: Connecticut, New Jersey 1, Michigan, Massachusetts, Quebec, Wisconsin, California, Ohio, Alabama, National Institute 504, New York 211, and Ontario. The homologous titers of these sera varied between dilutions of 1:2,560 to 1:10,240 with the exception of the Wisconsin serum which developed a titer of only 1:1,280.

* A duplicate of this culture was obtained from the New York City Laboratories 3 months after this work was completed. Identical results were obtained.

The results obtained when testing the 24 strains against these prepared sera are given in Table II. In these sera in most instances the *Proteus* strains, except for the known variants, gave agglutinations which approached very closely the homologous titers. On the other hand, the variants agglutinated only slightly or not at all.

Agglutination of Known Variants in Heterologous Sera—Since in our previous study it was demonstrated that variants of *Proteus* X19 strains would agglutinate in heterologous sera, all the known variants used in this study were tested against *Eberthella typhi* (Michigan), *Eberthella typhi* 'O' (New York), *Shigella paradysenteriae* Army, *Salmonella schottmuelleri* and *Salmonella enteritidis*. The OXK and HXK strains showed practically no

agglutination with the above heterologous sera. Only slight agglutination was obtained with the Storrs Smooth and Storrs Mucoid organisms, whereas the Storrs Rough Mucoid organism showed definite agglutination in all 5 heterologous sera, the titers varying from 1:80 to 1:320.

Agglutination of Heterologous Organisms in Known Proteus Sera—All 12 of the *Proteus* sera prepared were tested for heterologous agglutinins using the following organisms: *E. typhi* (Michigan), *E. typhi* 'O' (New York), *Shigella paradysenteriae* Army, *Salmonella schottmuelleri*, and *Salmonella enteritidis*. Five of these *Proteus* sera (Michigan, Ohio, National Institute 504, Connecticut, New Jersey 1) showed agglutinins for all the above heterologous organisms, ranging in titers from

	Homologous sera strains	2560—10240

NOTE: The absorption of each of the above 11 *Proteus* sera with homologous organisms removed completely both homologous and heterologous agglutinins. The 12th sera (Wisconsin) prepared showed no

1:80 to 1:640; 6 *Proteus* sera (Quebec, Ontario, New York 211, California, Alabama, and Massachusetts) showed agglutination only with *Shigella paradysenteriae* Army with titers ranging from 1:80 to 1:160; 1 strain (Wisconsin) did not develop demonstrable agglutinins for any of the above heterologous organisms. These results are included with the agglutinin absorption tests in Table III.

On the basis of these results the 12 *Proteus* strains were divided into 3 groups. In Group I were placed the Michigan, Ohio, National Institute 504, Connecticut, and New Jersey strains, each capable of developing agglutinins for 5 heterologous organisms; in Group II were placed the Quebec, Ontario, New York 211, California, Alabama, and Massachusetts X19 strains, each developing agglutinins for *Shigella paradysenteriae* Army only; in Group III was placed the Wisconsin strain which did not develop agglutinins for any of the 5 heterologous organisms with which it was tested.

Agglutinin Absorption—Our previous study of heterologous agglutinins in a *Proteus* X19 serum had shown that these agglutinins were bacterial group agglutinins and not due to the presence of heterophile components also present. In order to obtain further information regarding the source of the heterologous agglutinins in 11 of the 12 *Proteus* sera prepared for this study, each serum of the *Proteus* strains in Group I was absorbed with each of the 5 heterologous organisms for which agglutinins had been demonstrated. Each *Proteus* serum in Group III was absorbed with 1 heterologous strain, *Shigella paradysenteriae* Army. Each serum after absorption was titrated for heterologous and homologous agglutinins.

Agglutinin Absorption Method—The agglutinating serum was diluted to a degree depending on the titer of heterologous agglutinins. These dilutions

varied from 1:10 to 1:20. Six ml. of the diluted serum was added to a 24 hour agar slant of the organism under study. With a platinum needle, the suspension was carefully emulsified in the serum. A small pledget of sterile absorbent cotton was dropped into the test tube and the suspension drawn up into a pipette. The cotton acted as a filter for gross particles. The suspension was pipetted directly to a sterile centrifuge tube, incubated in a water bath at 37° C. for 2 hours, and then centrifuged at high speed for 1 hour or until supernatant fluid was clear. The supernatant fluid was then pipetted under sterile conditions onto a second 24 hour slant culture and the procedure repeated. The procedure was then repeated on a third slant. (This third suspension may be placed in the ice box over night with equally good results.) Absorption with homologous organisms using this technic is usually complete.

The results of the absorption of 11 *Proteus* sera with heterologous organisms are given in Table III. It will be noted that in general the titers of unabsorbed *Proteus* sera with heterologous organisms ranged between dilutions of 1:80 and 1:640. The absorption of these sera with heterologous organisms removed not only the agglutinins of the absorbing strain but also all other heterologous agglutinins known to be present. These results indicated that we were dealing with group agglutinins. Since no heterologous agglutinins were demonstrated in the Wisconsin serum no absorptions with heterologous organisms were made.

In an attempt to determine whether the 12 *Proteus* strains for which no sera were prepared had heterologous antigenic components, representative sera of Groups I and II (above) were absorbed with each of these strains. The absorbed sera were then titrated for heterologous agglutinins. Consid-

erable difficulty was encountered in effecting complete absorption for the absorbing strain in several instances. This was particularly true of the representative sera chosen from Group I. However, heterologous agglutinins were removed with comparative ease from Group II sera which contained the *Shigella paradysenteriae* Army agglutinins only.

The OXK and HXK strains did not remove heterologous agglutinins from the sera of either Group I or Group II indicating that these 2 strains do not contain antigenic components similar to those in the heterologous organisms studied. On the other hand, satisfactory controls of these absorptions were not possible due to lack of agglutination of these 2 organisms in the sera employed.

The Storrs Rough Mucoid, Storrs Mucoid, and Storrs Smooth strains absorbed heterologous agglutinins from a representative serum of Group I, indicating these organisms contain antigenic components in common with all the heterologous organisms studied. Two of these, the Rough Mucoid and Mucoid variants, also absorbed heterologous agglutinins from Group II serum. The Storrs Smooth strain, however, failed to do so but its titer in the serum was so low that no satisfactory control was possible and this result was, therefore, inconclusive.

The Storrs X19, American Type Collection, New York State 32,276, New Jersey 2, New York City, Massachusetts X2, and Norton 50, strains did not absorb heterologous agglutinins consistently from Sera of Group I but did absorb heterologous agglutinins from sera representative of Group II in all instances. This suggests that these strains do not contain heterologous agglutinogens similar to those present in the sera Group I but do have the *Shigella paradysenteriae* Army component corresponding to that in Group

II. Since no sera were prepared for these 7 strains, we do not feel that the results are consistent enough to warrant definite classification of these particular strains into groups. Although there is some evidence from this portion of the investigation that the group agglutinogens present in Group I differ from the *Shigella paradysenteriae* Army agglutinin in Group II, it was found that the absorption of Group I sera with strains representative of Group II, and *vice versa*, removed in the former absorption all heterologous agglutinins and in the latter, as would be expected, the component for the Army strain. In view of these results, it would appear that the organisms in Group II not only contain the Army antigenic component but also components (although masked) for the other heterologous organisms evident in Group I since the absorption of a Group I serum with a Group II strain removed completely the heterologous agglutinins present in this serum.

AGGLUTINATION WITH SERA FROM CLINICAL CASES OF ROCKY MOUNTAIN SPOTTED FEVER

In order to determine the efficiency of these strains in the Weil-Felix reaction—sera * from known clinical cases were titrated against all 24 *Proteus* strains used in this investigation as well as a variant described in a previous paper (*loc. cit.*). With the 19 diagnostic strains the titers were roughly comparable and in no case did we find any marked differences. The variant strains, however, with the exception of Storrs

* We are indebted to R. R. Parker, Ph.D., Special Expert of the U. S. Public Health Service, Rocky Mountain Spotted Fever Laboratory, Hamilton, Mont., for these sera. Since completion of these results several typhus sera have been received from H. Mooser, M.D., Pathologist, American Hospital Laboratory, Mexico City, Mexico, and from S. W. Bohls, M.D., Bureau of Laboratories, Texas State Department of Health, Austin, Tex. The results obtained with these sera were comparable with those obtained with the sera received from Dr. Parker. The authors express their appreciation to all who furnished sera for this study.

Rough Mucoid showed no agglutination in dilutions greater than 1:80. The Storrs Rough Mucoid strain showed titers of 1:160 to 1:320, which were comparable in many instances with titers obtained with normal diagnostic strains.

DISCUSSION

The finding of pleo-antigenic variants of a *Proteus* X19 strain was reported previously. At that time the importance of the phenomenon to public health workers induced us to continue this investigation in a study of diagnostic strains from the United States and Canada in an attempt to determine whether other strains either had present in them dissociates or the inherent capacity for producing them as evidenced by the presence of heterologous agglutinogens which can be demonstrated only by animal injection (Welch & Poole¹). In this study two major problems presented themselves: (1) To study the morphology of the cultures to determine the possible occurrence of variants and to identify them definitely as such; (2) to determine whether there were present in the sera from these strains components for heterologous organisms.

It was found that the 19 diagnostic strains on receipt in these laboratories did not contain variants comparable to the one previously described. Some morphological and biochemical differences were noted but these could not be correlated with differences in serological behavior. It was found, however, that only 6 of the 19 diagnostic strains were non-motile in spite of the fact that in several instances the motile strains had been obtained from originally non-motile cultures. For example, the Ontario, Quebec and New York 211 strains were all originally obtained from a single source. In this investigation the Ontario strain was the only one of these 3 retaining its original non-motile

characteristics. This in itself is indicative of the necessity of making frequent checks on *Proteus* X cultures used for diagnostic purposes which should be preserved in a non-motile state. An alternative to this is the use of an alcoholized suspension prepared according to the method of Bien and Sonntag.¹

Since sera for only 12 strains were prepared, definite proof of the presence of heterologous agglutinogens could be obtained only for these strains and the antigenic make-up of the remaining strains could only be inferred from cross-absorption studies. Our results indicated that heterologous agglutinogens were present in 11 of the strains for which sera were prepared. Although it was possible from an interpretation of these results to divide these organisms into 3 groups depending upon the number of heterologous components present, we do not feel that our inability to demonstrate certain antigenic components by direct agglutination in sera of organisms of Group II obviates their presence, especially since absorption of Group I sera with Group II organisms removed all heterologous agglutinins from the Group I sera. Apparently antigenic components in common with the *Eberthella* and *Salmonella* groups are present in the Group II strains in addition to 1 of the *Shigella* group but these are more effectively masked or more firmly fixed than in Group I. We found no evidence for the presence of heterologous components in the 1 strain in Group III. The major points brought out by the serological studies are: (1) that in general the *Proteus* X strains studied contain heterologous agglutinogens which may not be demonstrable by direct agglutination, and (2) that the variants studied are not agglutinable to any degree in sera from clinical cases and, furthermore, may contain free heterologous agglutinogens which may cause confusing, nonspecific reactions if present in diagnostic cultures. Our re-

sults with the 19 diagnostic strains used as antigen for the Weil-Felix reaction in sera from known clinical cases indicated their suitability for this purpose. On the other hand the variants with the exception of Storrs Rough Mucoid showed very slight or no agglutination with these sera.

The presence in the *Proteus* strains studied of heterologous agglutinogens which are demonstrable on injection into animals, coupled with the fact that dissociation of the organism may free these agglutinogens (previously demonstrated) so that they may be demonstrated by direct agglutination, indicates the necessity of a periodic morphological and serological examination of these strains. The use of such examinations will eliminate inagglutinable, spontaneous dissociates from the cultures, insure the retention of the strains in a non-motile state and disclose the presence of any free heterologous agglutinogens.

SUMMARY AND CONCLUSIONS

1. The morphological and biochemical characteristics of 19 diagnostic *Proteus* X strains and 5 variants are reported in detail. Marked differences in these characteristics were not noted except for the finding of 13 motile strains in the diagnostic group.

2. Heterologous antigenic components in common with the *Shigella*, *Eberthella* and *Salmonella* groups were shown in 11 *Proteus* X strains. Although these

were not demonstrable by direct agglutination in heterologous sera, they were demonstrated in the antisera produced by them on injection into rabbits or failing this, by their ability to absorb heterologous agglutinins from other *Proteus* sera containing them. Only 1 of the strains for which sera were prepared showed the entire absence of heterologous components.

3. The heterologous agglutinins present in *Proteus* X sera were shown to be bacterial group agglutinins.

4. Known variants of *Proteus* X strains were shown to be practically inagglutinable in sera from clinical cases of Rocky Mountain Spotted fever and, in addition, certain of these variants would agglutinate directly in heterologous sera.

5. On the basis of these findings it is recommended that *Proteus* X strains used in the Weil-Felix reaction be checked at least once a month to insure working with a non-motile culture and at least once each quarter to exclude spontaneously occurring variants.

POLIOMYELITIS IN CALIFORNIA

WE have already said that the symposium on poliomyelitis was perhaps the most interesting single feature of our recent meeting in California. While we intend to give our readers the benefit of these papers which go into the details of the various questions involved, on account of the wide interest in the epidemic, it seems that we should at once give a bird's-eye view, so to speak, of the situation.

At once it may be said that the peak of the epidemic occurred in June, and since then, there has been a steady and marked decline, though cases have continued to appear, chiefly in Los Angeles City and County. Many more cases than usual have been seen in other parts of the state, especially Fresno County, and apparently there has also been some spread to the states contiguous to California. San Francisco, usually regarded as the largest city in the state (though the editor was recently called to order by some southern Californians on account of this statement) has been very free, and for some time past has run from 1 to 3 cases per week, the report for the week ending September 15, 1934, showing no cases.

There are several features of this epidemic which are unusual. Beginning in May, it was earlier than most poliomyelitis outbreaks. There has also been a decided shift in the age period of those affected. Five epidemics have occurred in California, beginning with 1912. That year 78 per cent of the cases occurred in children under 8 years of age, while for 1934 to date, only 44 per cent have been under 10 years of age, and the number of adults affected has been comparatively large.

The mildness of the disease has been characteristic. In San Francisco, with a small number of cases, the death rate has been 6.8 per cent; in Fresno County, which continues to have the largest number of cases next to Los Angeles County, the death rate has been 2.3 per cent, while in Los Angeles County, it is only 1.5

per cent. As of the 6th of September of the year 1934, there have been 2,732 cases.

An outstanding feature of this epidemic has been the high infectivity, as shown by the high percentage of households which had multiple cases, 22 per cent of all cases having occurred in such households.

The high infectivity of this outbreak is also shown by the great number of doctors, nurses, other attendants and workers about the hospital who have become infected. In Los Angeles, where 95 per cent of the cases were hospitalized in the General Hospital, 137 such infections have taken place, the greatest number having been among the doctors (15), nurses (58), and student nurses (39).

Apart from the epidemic in general, great interest attaches to the methods of prevention and treatment. In the General Hospital, 121,000 c.c. of serum, approximately 55,000 of which was from convalescents, were used. Blood was also taken from normal adults over 30 years of age. Whether from convalescents or from normal persons, the serum from 10-20 individuals was pooled. It was preserved chiefly by a 1:10,000 solution of merthiolate, and was always kept 5 days before use. Both aerobic and anaerobic cultures were made from each lot. There was no control as far as treatment went, since the authorities did not feel that it was justifiable to withhold serum from any patient. As far as its prophylactic use, there was some control, owing to the refusal by a certain number of persons to accept it. There is some difference of opinion as to its effect. Some feel that the symptoms were milder in those who received serum, and instances of relapses are given, 3 in one case, in which each time there was a marked and rapid amelioration of symptoms after the administration of serum. There were fewer cases of muscular involvement and paralysis among those who received serum, though the number of cases is too small to admit of positive conclusions. The one point which seems to stand out clearly is that there was no difference in value between adult serum and convalescent serum. There were no marked ill effects, though there were some cases of more or less severe serum sickness, and in some, acute pain at the time of infection, especially in those in whom the administration was intramuscular. So far as figures go, the prophylactic use of serum was not successful. Employees who received serum showed a slightly higher degree of infection than those who did not, and this was true also of those working in the Contagious Disease Unit.

It should be clearly recognized that all reports so far must be regarded as preliminary. We have the spectacle of a community provided with well manned hospitals, amply sufficient for ordinary and even peak loads, being very rapidly overwhelmed by an epidemic of unusual proportions. The illnesses among doctors and nurses cut down the personnel and forced the employment of medical and advanced students in some types of work.

Needless to say, all sorts of conditions have been incriminated, such as swimming pools, bathing beaches, milk and water supplies, etc. If one thing stands out more clearly than another according to present information, it is that personal contact is responsible for the spread. Of those working in the Contagious Disease Unit, 14 per cent were infected as against 4.5 per cent for other parts of the hospital.

The papers from the Symposium will appear in an early issue of the Journal

PREVENTION OF FLY BREEDING

- WITH SOME NOTES REGARDING INSECT-BORNE DISEASES

IN 1931 the League of Nations Health Organization requested schools of hygiene to study flies and the best methods of treating manure heaps to prevent their propagation.¹ The Nancy Institute of Hygiene felt that this was especially deserving of its attention because of the fact that many parts of France were unfavorably known from the hygienic standpoint for the heaps of stable manure, often containing also the excreta of both normal and sick human beings, which stand before the houses along the streets in the villages. During the World War improvement was forced by the military authorities, but the farmers have returned to this ancient custom which dates back to immemorial times, and seems to be due in part to the actual structure of the old villages and the topography of the country.

The report contains much that is of interest. Experimental work has shown that individual flies without distinction of origin may carry from 60,000 to 25,863,000 germs, and in the case of flies captured near manure heaps, an even greater number. A large proportion of these organisms are colon, indicating the fecal source of the pollution. The report gives in some detail the methods by which these numbers were determined. Other experiments showed that milk (500 c.c.), when a single fly is placed on the surface, and left in contact with it for 30 minutes, then kept for 24 hours, will contain as many as 10,220,000,000 germs per c.c.

The authors have studied the effect of exposure to the sun as a method of sterilization of flies. When individuals taken from town flats and which showed 2,540,000 colonies at the time of capture were exposed for 2 hours to the sun, the number fell to 160,000. In flies taken near manure heaps and which showed at the time of capture 32,560,000 germs, only 6,720,000 remained after similar exposure to the sun, showing the destruction of 25,840,000 bacteria. From these experiments they hold that the bactericidal action of the rays of the sun is extremely powerful. Needless to say, it varies with the season, and the authors point out that their experiments are valid only for the months of July and August, when the light was most intense.

The report closes with a consideration of some methods of preventing breeding of flies in manure. In treating manure the agricultural value must not be destroyed, as it is one of our most valuable fertilizers. The authors favor the so-called Roubaud's biothermic method, and show that a temperature of 60° C. can be obtained in manure heaps by fermentation. They describe also a method in which by watering once or twice a day, a still higher temperature is reached, a desirable feature, since larvae, probably under the influence of the heat of fermentation, tend to come to the surface. They advocate the construction of 3 water-tight chambers with a ventilation shaft protected with wire gauze, a trap door for filling and a door for emptying, a sloping floor with channel to convey the liquid content to a cemented tank. Such an arrangement, which they describe in some detail and illustrate, does not destroy the fertilizing value of the manure and appears to accomplish the desired result.

As far as one can judge from the report, the authors are happily oblivious of the enormous number of studies carried out by Americans, of which we can mention only a few. As far back as 1897, L. O. Howard, Chief of the U. S. Bureau of Entomology, began to work on the subject. In July, 1914,² there was

published a bulletin on the subject, the result of consultations with other members of the department, and a large amount of careful work. The prevention of fly breeding in manure was the chief point of attack, and the preservation of the fertilizing value of manure was kept in mind. For this purpose treatment with borax 0.62 lb., or 0.75 calcined colemanite to 10 cu. ft. (about 8 bushels) was recommended. In May, 1915, an excellent bulletin was published by William B. Herms.³

As far as the carrying of disease by the house fly goes, Americans should remember the report of the commission composed of Victor C. Vaughan, E. O. Shakespeare, and Walter Reed, Vaughan alone surviving long enough to make the report. This was a study of typhoid fever during the Spanish-American War in 1898. It was clearly shown that in the camp at Chickamauga Park the food was contaminated by flies which had fed on fecal matter in the latrines and traveled from there to the tents. Many studies since have shown that the fly is capable of carrying many other diseases, and does so in some cases, particularly those of the intestinal tract.

The work of the Merchants' Association of New York deserves particular attention, 2 notable volumes having been published, the first⁴ in 1907, and the second⁵ in 1909. The first of these is a report of a careful experimental study by an expert. The second is a collection of opinions and facts obtained from a large number of health officers. Both, however, show that nearly 30 years ago even a body of laymen in this country had appreciated the danger of the fly to public health, and taken preventive measures against it.

America has been keenly alive for many years to the danger not only of the fly, but of insect carriers of disease. We can go back to 1848, when Dr. Josiah C. Nott incriminated the mosquito as a carrier of yellow fever. Dr. Carlos Finlay (1881) believed that he had proved the agency of the mosquito now known as the *Aedes aegypti* as a vector. This was finally proved by the U. S. Army Commission headed by Walter Reed, who made its first report in 1900. The first positive proof in the world that we know of concerning the agency of insects in carrying disease was given in 1893 by Theobald Smith, of the U. S. Bureau of Agriculture, when he showed that a tick carried Texas fever to cattle. McCoy, and other officers of our Public Health Service, made extensive studies of bubonic plague, and added much to our knowledge of its mode of spread, though to Ogata, 1897, belongs the credit of first showing the agency of the flea in transmitting the disease now known as tularemia. In 1919, Francis showed that the so-called deerfly fever was due to *B. tularensis*, harbored in jack rabbits and conveyed to man by the bite of the fly, *Chrysops discalis*. Rocky Mountain spotted fever, transmitted by the *Dermacentor andersoni* and *D. modestus* has also been worked out chiefly by Americans, and of late years chiefly by members of our Public Health Service, which now maintains a special laboratory for the purpose. The names of Wilson and Chowning (1902), King (1906), Ricketts (1906), Parker and Spencer (1923) are inseparably associated with our knowledge of this fatal disease.

Craig, in 1907, held that dengue was due to a filtrable virus and conveyed to man by a mosquito. A U. S. Army Commission, Siler, Hall, and Hitchens, gave final proof that the intermediate host is the *Aedes aegypti*. We also owe much of our knowledge of typhus fever to American workers. Ricketts and Wilder, Goldberger and Anderson, Maxcy, and the American Red Cross Commission, 1922,

deserve mention. Wilder, in 1911, produced strong evidence that the body louse was the exclusive infecting agent.

An American Commission also did good work on trench fever during the World War (1917), though credit for having discovered the cause of the disease must be given to McKee, Renshaw and Brunt, of England (1916).

In bringing up these matters, we do not mean in any way to belittle the excellent report to the League of Nations which has led to this discussion, nor the splendid researches done by scientists of other countries, but we are convinced that our people are entirely too prone to forget work done on this continent and to praise that done by foreigners. Even our leading medical journals are guilty of this fault. While Americans are sometimes described as bumptious and aggressive, we have been guilty of not giving due credit to our scientific men, at least as far as literature goes. "Honor to whom honor is due."

THE CCC CAMPS

ALL those interested in public health have been watching with much interest some of the efforts being put forth by the New Deal. Pretty nearly all of these have had a shower of brickbats thrown at them, some perhaps deservedly. One great exception is the CCC camps.

There was much incredulity when these were organized, the first one being near Luray, Va., in 1933. Since that time the number has increased to 1,643.

Attempts to get accurate figures from Washington have failed. There can be no doubt, however, that upward of 500,000 young men have been directly affected through their experience in these camps. Their moral tone has been raised, their health improved, and much done in the way of education to fit them for citizenship. It is known that thousands of young men have left home and have been tramping all over the country for want of something better to do. The CCC camps have helped in this situation, though much remains to be done.

Apart from the men themselves, it is stated that 315,000 families have received from \$22 to \$25 a month from the young men in the camps whose basic pay is \$30 a month. It is safe therefore to say that considerably more than a million people have been directly helped through the operation of this Corps. It has overcome the incredulity and opposition felt at the beginning, and seems to have won a high place in the estimation of the public.

PUBLIC HEALTH EDUCATION*

"Whereas . . . Be It Resolved"—The resolutions passed at the Pasadena meeting of the A.P.H.A. may well be scrutinized for leads by him who writes or speaks—as well as by him who plans in the department or association.

Some of the resolutions seemed to point to popular health education subject matter. Some resolutions become copy material only after they have been passed upon in relation to department policies and programs. But they are worth looking into.

The Unusual at Pasadena—The space available for scientific and educational exhibits was so generous and the response was so enthusiastic as to set a new record in extent and variety of material for study offered to delegates. Doubtless many of us will look forward to what will be available at Milwaukee in 1935. *It all depends upon what the public and private agencies—national, state and local—will plan for during the months ahead.*

Flashes and Close-Ups—At Pasadena we caught flashes of ideas and projects which have not been revealed to health education workers in other states and cities. We managed to take a few notes and hope to write a few letters. But such efforts by the editor will cover but a small section of the unknown.

Why not be able to say: "We do our part" and "We have shared"?

We are sure that *Journal* readers

would value details of the colored-paper-on-map technic developed by Guy P. Jones, and the staff information service conducted by Miss Brown of the Los Angeles County Department, and Virginia Wing's "charm" campaign, and some details of what Dr. Galdston hinted at in the Members' Meeting. These are but samples of what we hope to receive from readers in all states and provinces *and* countries.

Give us close-ups, please.

"There Are No Dull Subjects"?—Signed "Little Sunshine" comes a flareback from the quotation in the September issue of the *Journal*:

There is something about your column that always incites me to comment.

On a busy day in the early fall I picked up your respected contribution to the *A.J.P.H.* (page 979) and what hits me in the face—me, a struggling, overworked, dried out editor? (Quote) There are no dull subjects; only dull writers (Unquote, and insert "there are" before second "only")! Slap! Just like that. All right. I challenge you.

Write me a brief very undull description of the aims of your A.P.H.A. department: Public Health Education.

Thank you.

I now take the great liberty of reversing your quotation and replacing the emphasis, to wit, namely:

"There are no dull writers; there are only dull subjects which have been placed in this world to eliminate all but the good writers." The trick then is to avoid the dull subjects lest they prove your Waterloo.

Who will be knight for the editor fair and take up this challenge? Who will write that "undull description of the aims" of the Public Health Education Section?

Possibly we should first set down those aims—dull or undull—unless

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Routzahn, 139 East 22d St., New York, N. Y.

someone will both set the aims and describe them.

In another month or so the editor of this department will think up worthy awards for any and all who take up this challenge on his behalf. We await chivalrous volunteers.

A Course in Adult Health Education—Master of Science in Public Health will be conferred on students of adult health education by the University of Michigan. "Graduate Programs in Public Health: 1934-1935-1936" announces the following course of study, with hours of credit noted at the right:

First Semester

Hygiene 201, Physiologic Hygiene—3
Hygiene 204, Vital Statistics—3
Education B182, Current Studies in Adult Education—2
Journalism 101, Feature Writing—3
Sociology 121, Community Problems—2
Speech 131, Advanced Public Speaking—3
—total hours—16

Second Semester

Hygiene 202, Community Health Problems—3
Hygiene 206, Public Health Law and Administration—3
Hygiene 210, Adult Health Education—2
Journalism 56, Community Newspaper—3
Sociology 147, Social Psychology—3
—total hours—14

Courses recommended for substitutions and additional preparation:

Journalism 51, 52 (prerequisites), Journalism 55, 102
Speech 132, Advanced Public Speaking
Sociology 111, 113, 116, 132, 147
Political Science 141, 142, Municipal Government

Hygiene 102, 107, 115, 118, 208, 209, 211
Education C102, C108, A125, A207

For further information, write to Dr. John Sundwall, Division of Hygiene and Public Health, University of Michigan, Ann Arbor.

At Your Finger Tips—Literally so is much health information through the Health Knowmeter which origi-

nated with the Association of Women in Public Health.

Hundreds of classified facts are supplied in question and answer form on mimeographed sheets. This material may be clipped and pasted on cards and filed for easy, quick reference by teachers and others. Address: Mary R. Lakeman, M.D., Health Knowmeter Comm., 100 Nashua St., Boston, Mass.

The American Medical Association has prepared for display at fairs, expositions, etc., questions and answers taken from *Hygeia* and copied on visible index cards.

This idea might be worked out by a teacher or health worker, clipping or copying questions and answers from a file of *Hygeia*.

"Why Not Let Them Die?"—"Health education needs a good housecleaning to do away with many superstitions that have grown up around it. In *Journal of Outdoor Life*, June, 1934, and again in *Michigan Out-of-Doors*, Lansing (July-Sept., 1934), Dr. Warren Forsythe discusses this subject.

The popular understanding of personal health rules needs a lot of debunking by the application of science.

Much of the traditional subject matter of personal hygiene has no better basis of truth than folklore, half baked ideas or personal opinions associated with an emotional bias.

Observations at Pasadena—Here is the first reply to a request for observations of the Public Health Education Section in action:

What seemed important to me:

The varied interests of those who attended the section meetings.

That increasing thought must be given to enriching Section programs because of these varied interests.

A consciousness of those who attended that most public health activities have a health education content.

That large numbers of persons are interested in techniques and materials.

Another commentator noticed that

certain speakers and some of the participants quite forgot the theme of the session. Or, possibly they simply took the opportunity to "get something off their chests."

A lack of an eager curiosity was noted by this same observer. Few speakers can anticipate all of the needed practical angles of what they present. Usually questions from the audience are needed to secure well rounded presentations. And usually, there were not enough of such questions. Did the speaker fail to interest us? Were we willing to guess at what was left unsaid? Did we fail to note the omissions? Were we sitting without thinking, waiting to be filled up without effort on our part?

Nevertheless, adds the editor, we had good papers; many eager, enthusiastic audiences; and the very special privilege of meeting numerous western comrades who seldom venture to the eastern meetings.

They Did Bring Address Cards— But some of the printed address cards left at Education and Publicity Headquarters at Pasadena *named no city*. We have seen a few letterheads, annual reports, and even survey reports with no mention of a city. What amazing modesty.

Teaching in a Clinic—How to make the most of a clinic for health education? One answer is given by Frances F. Hagar in a discussion of the most productive nursing service with a limited personnel:

Probably the most important function of the clinic is teaching. This is a point that will bear a most searching and intelligent study. Consider the whole set-up of the clinic. Is it planned so that the teaching may be done in a systematic manner? Has the nurse delegated responsibilities to her assistants in such a way that she is free to supplement the teaching of the doctors and to explain matters which might be somewhat

confusing to some persons? Is the teaching conducted along such a line that it might replace the costly home visit? How much demonstration material is used for teaching? A certain amount can always be used to advantage. Is group teaching a practice? The group conference is a very practicable method of teaching. Through discussion, many points are stressed which might be lost in the individual conversation. The group conference combined with the individual conference is particularly well adapted to the antepartum service.

In order to make clinics more productive, then, might it not be worth while to have a critical analysis of this service. Study it from all angles to see where it might be improved in the matter of time and work of personnel, as these relate to the amount of service which can be rendered in a given community.

In *Child Health Bulletin*, Am. Child Health Assn. (Sept., 1934), 50 W. 50th St., New York, N. Y. Single specimen copies to non-members, 10 cents.

Fewer Figures, More Interest—A recent state fair exhibit of Ohio State Department of Health was

. . . not so elaborate, or diffuse, as some that have gone before, and did not run so much to statistics as most of them; but it spoke its piece in easily understandable language, and drew—and held—the crowd accordingly.

New among its features, a real "sign of the times," was the occupancy of a booth in the departmental space in the Manufacturers' Building by official representatives of the Ohio Federation of Women's Clubs, who distributed several thousand pieces of literature, including as major items material on children and diets and the three major degenerative diseases—cancer, heart disease and diabetes. Their presence in the departmental space is the first step in the Federation's campaign in promotion and support of official health agencies, state and local.

Departmental literature was handled at the other end of the departmental display, and a large sheaf of signed requests resulted, calling for several thousand pieces of printed health material. . . .

An attractive model of a modern sanitary swimming pool attracted much attention and resulted in many questions. Vital statistics was presented in a few crisp statements of fact, instead of in many columns of figures. The essential facts sought to be enforced

were "driven home" under the new method in a way which no column of figures could do. The new method, therefore, is a great improvement over the old.

Chest films of tuberculosis, in shadow-boxes, added much interest to the display of the Bureau of Tuberculosis, which was not without other attractive features. The departmental laboratory was another division which made the major part of its display in new guise. Instead of having several microscopes, worth hundreds of dollars, on the table for the curious to use in exploring the depths of drops of water, blood, etc., for "bugs" and corpuscles, there were drawings in color of the microscopic field, showing the different types of germs, drawn to scale and of large size, prominently displayed. . . .

Dr. Johnson's model sanitary privy, built on the grounds northwest of the building which housed the other features, attracted a constant stream of visitors and, coupled with the placarded table of materials and costs, and explanations by those in charge, resulted in the actual sale of many and the probable sale of several thousand. These privies are being constructed as a feature of federal relief work in more than 60 Ohio counties.

Other divisions of the department were represented by "small but effective displays."

"Three Health News Features"

—Under this heading, in *News Bulletin* of Social Work Publicity Council, (Sept., 1934), 130 E. 22d St., New York, N. Y., appears the following:

A series of brief health editorials are being supplied to the *Cincinnati Times-Star* by the Cincinnati Public Health Federation. They appear every day under the heading "Save a Life," and a tailpiece "Perhaps Your Own." Monotony is avoided by having the articles cover all sorts of subjects connected with public health, including the prevention of accidents, particularly motor ones. A typical one reads:

"About 60,000 people die annually in the United States of pneumonia. A great many of these deaths could be prevented if people would take better care of themselves. A bad cold is often the forerunner of pneumonia. If you catch a cold, don't neglect it. Go to bed if you can, but above all don't perform exhausting work, remain in a draft, or subject yourself to exposure in bad weather. And call your doctor promptly if there is fever."

Starting in mid-August, out in Honolulu, the *Hawaii Hochi*, a daily newspaper published in Japanese and English is running a bi-weekly two-page child health supplement, sponsored by Palama Settlement and the local Tuberculosis Association. We are watching with interest, as other plans of this kind have not always worked out successfully. So much depends on the delicate balance of good faith from both sides. James G. Stone writes us: "We sense the possible danger of unreliable advertising, so it has been agreed that all advertising copy for this special supplement shall also be approved by us. The names of potential advertisers are being submitted to us for approval before the advertising department makes the contact with the advertisers. All proprietary remedies have been definitely ruled out."

A restrained factual article, "Plague," in the *Baltimore Evening Sun*, Aug. 13, 1934, shows H. L. Mencken in a new mood. He discusses in useful paragraphs the problems in the control of syphilis. He even mentions social workers without any derogatory comments: "Since the War it (syphilis) has been widely discussed by medical men and social workers, and the old taboo upon any mention of it has largely broken down." This change in the general attitude toward syphilis and the change on the part of the medical profession so that the regulations on reporting it to health departments are being more carefully followed out are the bases of Mr. Mencken's article. His name, as author, should have a good deal of weight with Baltimore newspaper readers.

Getting Acquainted with County Commissioners—A possible weak point in the support of the public health agency is the educational work done with legislative and budget-making bodies—city, county and state.

Dr. C. H. Douthirt states some examples of omission, then says:

I suggest that every health officer in the state attend every regular meeting of the county commissioners. It isn't necessary to stay all day, but go in, sit down with them and discuss the health work in the county. Tell them what you and the nurse are doing, your plans and problems; give them copies of your reports to the state and your mileage reports. Ask for suggestions and criticisms. Tell them you want to cooperate with them and then show that you mean it by attending their meetings. Get acquainted with your county commissioners; they are all good fel-

lows, and more than that they have been selected by the people to run the business of the county.

In *New Mexico Health Officer*, Santa Fe, Aug., 1934.

Where to Write for Help—Some teachers may be encouraged to seek supplementary references and materials for their classes. Other teachers are compelled to seek whatever material they need because none is officially provided or suggested.

In *Hygeia* (Oct., 1934) Dr. Thomas D. Wood says:

Under any circumstances finding the best helps for health teaching is a stimulating, challenging and somewhat difficult or complicated game for the classroom teacher.

Dr. Wood tells of the part taken by supervisors or counsellors, when there are such. Then

Health knowledge as differentiated from health teaching methods involves a wide range of authentic information regarding the many aspects of health.

The sources for such material discussed by Dr. Wood include governmental agencies, national health and welfare associations, commercial or business organizations, and popular monthly and weekly as well as daily periodicals. Some of the pitfalls are pictured.

To those who may consider the suggestions or advice in this article lacking in definiteness, let it be confessed that the writer believes firmly that teachers in many instances cannot be sure of the best places to look for help for health teaching without expert advice in this field, which is fundamentally the most important and at the same time the least exact of the applied sciences.

We are glad that Dr. Wood has emphasized this need of "expert advice." There was no space for him to have gone further, but we hope that he or someone else will attempt to point out in a future article just how teachers may go about getting the right kind of help from local and other authorities,

and how local groups of teachers may make up for the absence of competent supervisors.

October, 1934, *Hygeia*—Here are a few of the topics presented in this issue:

What is sinus trouble? (how it may be prevented, what to do for it). The handicapped child (what the parent should and should not do). Food fads and faddists (a debunking of some well known diet theories). The head louse (one of Our Parasites). Common sense in mouth care (about brushes and brushing). New books on health. Questions and answers.

School and Health includes: The place of the textbook in health education. Where may teachers look for help in health teaching? New health books for teachers and pupils.

Syndicated Health Education—The annual "Directory of Features" in *Editor and Publisher*, Times Bldg., New York, N. Y., lists health columns by the following authors now being sold to newspapers by syndicates and services:

Drs. Logan Clendening, Morris Fishbein, Royal S. Copeland, Sophia Brunson, W. F. Thomson, Iago Galdston, William Brady, Michael Shuman, H. J. Hoare, C. N. Chrisman and James W. Barton—and Dr. Frank McCoy. (Sept. 29, 1934. 10 cents.)

Damaged Lives No Longer Sponsored—Next month we will explain how undesirable promotion of the "Damaged Lives" motion picture has caused American Social Hygiene Association to withdraw its sponsorship.

Please report to the Association, 50 West 50th St., New York, N. Y., any showings of the picture.

CORRECTION

Under "Magazine Articles" (June, 1934) the price of *Today* should be 10 cents a copy.

DISCONTINUED

Health Officers' World, Milwaukee, has been temporarily discontinued, and no copies are available of issues we have mentioned.

EVENTS AHEAD

Roll Call of the American Red Cross in November, and the Christmas Seal Sale of tuberculosis associations in December are of special interest to health agencies.

The 1934 Mobilization for Human Needs, Oct. 28 to Nov. 11, particularly concerns health agencies in community chest cities.

The National Tuberculosis Assn. announces that it sent to state tuberculosis associations early in September samples of the materials to be used in the E.D.C. for 1935. The slogan and keynote: "Fight Tuberculosis With Modern Weapons." Objective: to spread information about treatment.

Quackery and fads still thrive; worn out theories and health fetishes still obstruct scientific treatment. It is our opportunity to dispel the unsound and displace it with the exceedingly hopeful story of modern treatment.

We now enter the season of state social work conferences. Probably all of them will have one or more health sessions. They are not likely to give time to health education unless health workers in the states take the initiative.

FOR EDUCATION AND REFERENCE

"Half a Century of Warfare against the Typhoid Fever Bacillus" is a brief summary, with diagrams, offering usable material for copy. *Statistical Bulletin*, Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

Monthly Letter, Housing Information Bureau, Welfare Council, 122 E. 22d St., New York, N. Y., is a mimeographed bulletin with housing news from all over the country, and rather full mention of books, pamphlets and articles. \$1.00 a year. Sample free.

It is a comprehensive analysis of a study by selected teachers over 6 weeks concerning

3,512 unselected pupils in 58 centers in up-state New York. It reveals deficiencies to be especially marked regarding habits of sleep, bathing and hand-washing, dental hygiene, balanced diet, over-fatigue.

Two reprints from Milbank Memorial Fund, 40 Wall St., New York, N. Y., copies free:

"A New Deal in Health Education," by Bertrand Brown.

"An Experiment In Health Education In Chinese Country Schools," by C. C. Chen, M.D.

Reprints and other pamphlets are offered by National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y.:

"Activity Program in Sight-Saving Classes." 5 cents.

"Automatic Light Control in the Modern School." 5 cents.

"Eye Hazards in Play." 5 cents.

"First Eyeglasses at Middle Age." 5 cents.

"Light and Vision." 10 cents.

"Preventing Blindness Through Social Hygiene Coöperation." 10 cents.

"A Program of Eye Health in a School System." 10 cents.

"The Romance in the Movement for the Prevention of Blindness." 10 cents. "Great causes begin with great personalities"

"Safe and Sound." Syphilis blood test for expectant mothers.

"Trachoma in the United States." 10 cents.

"Vocational Guidance for Children with Defective Vision." 10 cents.

Single copies of the above free to health workers.

INFORMATION WANTED

American Social Hygiene Assn., 50 W. 50th St., New York, N. Y., would

like to receive from social hygiene societies, hospitals, clinics, or individual workers, any data available concerning education of patients while under treatment as regards their present condition and future health. A *Popular Health Instruction* number of the *Journal* is contemplated during the fall, for which such material will be especially useful.

BOOKS AND REPORTS

Death Rates by Occupation—By *Jessamine S. Whitney*. New York: *National Tuberculosis Association*, 1934. 32 pp. Price, \$1.00.

The almost complete lack of official occupational mortality rates by age and cause of death in the United States for any considerable number of occupations, has been a serious deficiency in our national vital statistics records. Industrial hygienists, vital statisticians, economists, labor officials, and others who have sought to determine and appraise the effects of occupations on health and longevity have suffered a handicap in mapping out campaigns for the amelioration of working conditions without this information.

In the introduction it is stated that up to this time no death rates by occupation have been available in the United States. While this is not strictly in accord with the facts, since death rates by occupation were published by the Bureau of the Census in connection with the 1890 and 1900 censuses, nothing has been published for over 30 years. These old data are probably inaccurate and certainly are not representative of present-day conditions. Mention might also have been made of the report of the Actuarial Society of America and the Association of Insurance Medical Directors entitled "Joint Occupation Study, 1928." Considerable light is thrown on the effects of occupational hazards by the death rates and ratios shown in that investigation.

The statistics published decennially by the Registrar General of England and Wales for more than 50 years have been the best guide to the effect on mortality of a large group of occupations. We

have not been able to do the same thing in the United States, mainly because of two considerations: (1) there is much greater shifting from job to job in the United States, and (2) there is greater accuracy in reporting the occupation at death in England and Wales. So many persons in the United States have been classified in general and unspecified occupational groups at death who were classified in specific groups in the census, that officials have felt that death rates for most occupations would not be valid.

As a result of an educational campaign of the editor and her coworkers, it was finally possible to select 10 states with data sufficiently accurate to compile occupational mortality figures. Thirty-nine per cent of all gainfully occupied men in the United States were found in these states which included part of the industrial East, the agrarian West, and one typical southern state. The general death rate for occupied males at specified ages in the 10 states corresponded closely with those for all males in the 10 states and in the U. S. Registration Area. The tabulations made by the Bureau of the Census were, of necessity, further limited to occupied males aged 15 to 64 in 1930, 53 occupation groups in which there occurred, in 1930, 500 or more deaths, and 17 specific causes of death.

To eliminate the influence of economic status, death rates are shown by age and cause, according to Dr. Alba Edwards' grouping of social-economic classes, with the exception that agricultural workers were grouped separately.

There are 8 tables and 1 chart. Standardized and age specific death

rates from 10 causes of death are shown for the social-economic classes and each of the 53 occupations. Table 1 presents a very valuable analysis of mortality by social-economic classes such as we have not had before, showing standardized and age specific death rates for all gainfully occupied males aged 15 to 64. It is rather unfortunate that the total for men in selected occupations is included in Tables 5, 7, and 8 as the basis for comparison for each occupation instead of the total of all gainfully occupied males. The net result is to give undue weighting to occupations with higher than average death rates and thus to raise the standardized death rate for all occupied males from 8.70 to 9.10. The standardized rates for each social and economic class and for each cause of death are also affected. This fact should be kept in mind when comparing death rates for a specific occupation with the general average.

The authors, who selected causes of death from the point of view of occupational hazard, included only 3 means of accidental injury. It is impossible, therefore, to tell what part total accidents played in the total mortality or in the mortality of the socio-economic or occupational classes.

A table giving the number of workers, deaths and death rates for most of the occupations in the Census Index of Occupations is included to show the necessity of selection for detailed study and to present significant figures for occupations excluded because the number of deaths was under 500. With the limitations of this table kept in mind, it will undoubtedly be of value. However, some measure of the position in the mortality scale, either through standardized death rates or ratios of actual to expected deaths might have been given for the larger occupations not included in the detailed study, especially where there was a high degree of correspond-

ence between the reporting on the census schedules and death certificates.

The comments of the authors on the tables are instructive but limited. Comments on the credibility of rates such as 910 for clerks (except those in stores), 772 for clerks in stores, and 693 for bookkeepers, cashiers, and accountants would have been helpful.

In spite of its inherent limitations, this report is a valuable addition to the all too meagre body of American statistics on occupational mortality. The data for social-economic classes are especially useful. Possibly the chief value of the work lies in the fact that it will keep alive interest in occupational mortality statistics in the United States and that it will serve as a groundwork for future studies. The difficulties which had to be overcome before this study could be accomplished were almost insurmountable. A debt of gratitude is owed to Miss Whitney "whose initiative, vision, and persistence made it possible." Acknowledgment is made in the report of the promotional work done by Miss Mary V. Dempsey and of the cordial coöperation and technical assistance of the staff of the U. S. Bureau of the Census.

ROBERT J. VANE

Hygiene for Freshmen—By Alfred Worcester, M.D. Springfield, Ill.: Charles C. Thomas, 1934. Price, \$1.50.

We have read this short book with pleasure and believe that it is constructed on the right principles, beginning with some anatomy and more physiology. The discussion of prevention of disease takes up only some 15 pages, and the subject of immunity 13 pages. The book begins with an introduction, following which biology and embryology are discussed. The next 8 chapters are devoted largely to physiological considerations, taking up in order

the circulation, glands, nutrition, digestion, etc. There is a glossary which strikes us as being insufficient for the average freshman. Each chapter is followed by questions which cover the contents.

It is doubtless bold for anyone to criticise the English of a Harvard professor. However, in some places the author changes abruptly from the impersonal to the personal, even in the same paragraph. Apparently the author forgot that he was writing a book and not delivering a lecture.

Altogether the book can be commended for the purpose for which it is intended. It is well printed and bound.

MAZŮCK P. RAVENEL

Text-Book of Meat Hygiene. With Special Consideration of Antemortem and Postmortem Inspection of Food-Producing Animals — By Richard Edelman, Ph.D. 6th Revised Edition, by John R. Mohler, V.M.D., and Adolph Eichhorn, D.V.S. Philadelphia: Lea and Febiger, 1933. 474 pp. Price, \$5.50.

A book which has gone through 6 editions has proved its value, and there is little or nothing to be criticised in the present volume. While it is dedicated to the veterinary profession, we wish very much that doctors, and especially health officers, would take more interest in this line of work, and absorb the sound scientific knowledge and advice contained in its pages. The editors have brought it up to the minute. It gives all improvements and changes in packing house methods and shipment, including the most recent knowledge concerning food poisoning and quick freezing.

Chapter IV is a reproduction of the regulations governing the meat inspection of the U. S. Department of Agriculture, including disposal of diseased carcasses, labeling, marketing, branding, reinspection, counterfeiting, exporting,

imported meat and products, and the handling and inspection of horse meat. An especially interesting chapter is the History of Meat Hygiene.

The book is a mine of information and can be recommended unreservedly to all interested in this most important branch of food hygiene. We wish for it a wide circulation.

MAZŮCK P. RAVENEL

Die Akuten Zivilisationsseuchen: Muesern, Pocken, Keuchhusten, Scharlach, Diphtherie, Epidemische Kinderlähme — Ihre Epidemiologie und Bekämpfung—By Dr. B. De Rudder. Leipzig: Georg Thieme, Verlag, 1934. 286 pp., 49 figs. Price, RM. 18 bd., RM. 16 unbound.

This treatise deals with the epidemiology and control of the acute diseases of civilization, namely measles, smallpox, whooping cough, scarlet fever, diphtheria, and epidemic infantile paralysis. The author is the director of the children's clinic in the University of Greifswald, and the book is written primarily from the clinical standpoint, but with emphasis on the relations of the subject to public health and state medicine. The book aims to present the basic facts of the epidemiology of these diseases in such a manner as to bring out the deficiencies in knowledge on the subject. Details of bacteriology and serology are omitted except in so far as they are related to therapy, control, or epidemiology.

The work is so very comprehensive in its scope that no brief review can adequately present it. For example, in dealing with infantile paralysis one finds, in addition to the many general topics concerned with the disease, discussions of the origins of centers of contagion, and of carriers, the contagiousness, the index of contagion and difficulties in determining it, variations in the period of incubation, family centers,

immunity and susceptibility, immunity without evidence of illness, extra-uterine origin of immunity, age distribution of immune individuals, the division of the population into groups of differing immunological relations, abortive attacks, periodicity influence of climatic factors, summer peak, and crippling effect.

Of especial value is the extensive survey of the principles of control and prevention by isolation, disinfection, quarantine, the carrier problem, vaccination, convalescent and adult serums, and standardization of serums and toxoids.

CHARLES A. KOFOID

Grundzüge der Hygiene—By Max Eugling. 3rd ed. Berlin und Wien: Urban & Schwarzenberg. 448 pp., 155 figs. in text. 1934. Price, M. 10 in paper, M. 11.80 bound.

The third edition of this comprehensive and informative handbook of hygiene has undergone a thorough revision of all sections with the addition of new material. The greatest expansion is in the subject of industrial hygiene, especially in industrial poisoning, a necessary consequence of the expansion of industrial chemistry. Sections on the control of communicable diseases, and the German and Austrian regulations on notification have been added. Many additions have been made to the sections on disinfection and infectious diseases. New statistics in social hygiene and new illustrations have been added.

Few, if any, books in this field have the breadth of vision, analytical display, lucidity of presentation, and inclusiveness which one finds in Professor Eugling's handbook. Teachers of the subject will find here a comprehensive and logical presentation of all aspects of hygiene. All those interested in public health will find here many suggestions in various fields which will widen the horizon of their interests and broaden the scope of their opportunities and obligations. CHARLES A. KOFOID

Seeing and Human Welfare—By Matthew Luckiesh. Baltimore: Williams & Wilkins, 1934. 190 pp. Price, \$2.50.

The point of view from which this book is written is that the human seeing machine should be supplied with a great deal more electric light than is ordinarily provided for it. The author undertakes to show why this is so and how the deficiency can be made up at small cost. He declares that millions of persons are being penalized every day for want of light, without knowing it, the result being a crippling of eyes, eye strain disorders, and an unnecessary expenditure of physical and nervous energy.

Seeing conditions, he says, are not necessarily adequate when the work can be done without conscious effort and with merely the required speed and accuracy. An adequate factor of safety should be provided. How large this should be or how it can be determined is not stated. Contrary to widespread belief, he says, it is hardly possible to have too much light.

Whereas an ideal condition is 1,000 foot-candles or the intensity existing in the shade of a tree a noon on a bright, sunny day, a great deal of the work of the world is done with an intensity of less than 1 foot-candle, or the light of a single candle at the distance of 1 foot. Three feet from a 100-watt tungsten filament lamp, the intensity of illumination is only about 10 foot-candles. These are called primitive conditions. The author recognizes that 1,000 candle power is more than can generally be provided in practice and would be satisfied with considerable smaller intensities, depending on the conditions under which the light would be used.

Intensities recommended by the author, without, however, stating any definite basis for them, follow. One hundred foot-candles or more for severe and prolonged tasks such as fine en-

graving; 50 or more for drafting, watch repairing and difficult reading; 20 to 50 for prolonged clerical work, reading, and bench work; 10 to 20 for office and factory work; 5 to 10 where fine details are not involved.

The low cost of current makes adequate lighting practicable so far as current is concerned, for it averages about 6 cents per kilowatt for residences and is sometimes less than that. At this rate, a 50 watt lamp has to burn 4 hours to cost 1 cent. The author says: "One can enjoy 100 foot-candles for reading an entire evening or for a large part of a day at the cost of a telephone call." The cost of installations, fixtures, lamps, and replacements are not mentioned, but often present a serious obstacle to proper lighting.

A reading of the book would convey a profound sense of the involved character of seeing, if anyone had any doubt about the matter. And it is but fair to say that the author attempts to deal with only a part of the broad topic he has chosen. He says that the science of seeing must deal with three major complexities which are interdependent and intermingled:

1. The external world of physical factors.
2. The eyes, visual sense and successive events of visual response.
3. The psycho-physiological effects pertaining to human behavior, efficiency, welfare and happiness.

The book has to do chiefly with the first of these complexities.

So far as public health workers are concerned, the principal use of the book lies in the simple way in which terms, facts, and arguments used by lighting experts are explained.

The author is director of the Lighting Research Laboratory of the General Electric Company, Cleveland. He has written over a dozen other books on subjects pertaining to light, and particularly artificial light.

GEORGE A. SOPER

Notes on Planning a Publicity Program—By *Mary Swain Routzahn*. New York: Social Work Publicity Council.

Social workers and publicity committee members looking for guide-posts to show them the way to plan a publicity program or to check over plans already afoot will find many suggestions in *Notes on Planning a Publicity Program*, just published. Mrs. Routzahn is Consultant in Social Work Interpretation of the Russell Sage Foundation.

In an informal way, Mrs. Routzahn brings up leading points for consideration in planning a program: the reasons for year-round programs; what publics the program tries to reach; what to tell; the forms in which information is available; and various publicity channels evaluated in relation to the public.

The pamphlet can be secured from the Social Work Publicity Council, 130 E. 22nd Street, New York, N. Y., for 15 cents per copy.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

John Bull's Children—The growth of the preventive aspects of school medical service in England is recounted. There the school child health supervision is much more closely allied to the other services which make up the general program of health improvement than is at present possible in this country.

ANDEN, G. A. School Medical Inspection in England. *Child H. Bull.* 10, 5:149 (Sept.), 1934.

Comparative Mortality—Industrial workers have mortality rates greatly in excess of those higher in the economic

scale; unskilled workers have the highest. Tuberculosis, pneumonia, and accidents are chiefly the cause. In England the difference is even more marked than here.

BRITTEN, R. H. Mortality Rates by Occupational Class. *Pub. Health Rep.* 49, 38:1101 (Sept. 21), 1934.

British Care of the Tuberculous—Early diagnosis and after-care of tuberculosis are the problems in Great Britain as they are here. Hence, what is being done there is of interest to us, too.

BURTON-FANNING, F. W. Our Difficulties in

the Conflict Against Tuberculosis. *J. State Med.* 42, 9:497 (Sept.), 1934.

Do People Die of the Heat?—Exceptionally high death rates appear to be associated with exceptionally high temperatures in a study made of conditions during the recent middle western drought.

COLLINS, S. D. Maximum Temperatures and Increased Death Rates in the Drought Area. *Pub. Health Rep.* 49, 35:1015 (Aug. 31), 1934.

Mottled Enamel of Teeth—Infinite amounts of sodium fluoride in drinking water—25 p.p.m.—produce changes in the teeth of rats, an indication of how small a dosage will injure teeth of humans as well.

DEAN, H. T., *et al.* Effect of Various Amounts of Sodium Fluoride on the Teeth of White Rats. *Pub. Health Rep.* 49, 37:1075 (Sept. 14), 1934.

When Budgets Are Cut—Intended to serve a local situation, the consideration of essential health administrative measures broadens out to make a most valuable and generally useful document.

EMERSON, K. Essential Public Health Services. *New Eng. J. Med.* 211, 10:451 (Sept. 6), 1934.

Something New Under the Sun—Sonne dysentery is endemic, of increasing incidence, and may change in epidemic form to affect more adults than in the present stage (in which it is confined largely to children).

FILSEN, J., and OSOFSKY, A. G. Sonne Dysentery. *J.A.M.A.* 103, 13:966 (Sept. 29), 1934.

When Youngsters Whoop—Vaccination with pertussis antigen reduced the severity of the whooping cough attacks, as compared with a control group, among children who contracted the disease after exposure.

FRAWLEY, J. M. The Immunization of School Children Against Whooping Cough. *J.A.M.A.* 103, 13:960 (Sept. 29), 1934.

More Praise for Breast Feeding—Among 20,000 babies cared for by the Chicago Infant Welfare Society, the morbidity rate of the artificially fed was nearly double the sickness rate of the breast-fed children, and the mortality rate ten times greater. Breast feeding is still the most potent protection against diseases of infancy.

GRULLEE, C. G. Breast and Artificial Feeding. *J.A.M.A.* 103, 10:735 (Sept. 8), 1934.

School Nursing Good and Bad—Information about the performance of school nurses is set forth in the survey by the N.O.P.H.N. There is much worth while discussion of the conditions and problems revealed.

HELBERT, H. Public Health Nursing Service to School Children. *Pub. Health Nurs.* 26, 9:461 (Sept.), 1934.

Rheumatic Children—Tonsillitis or sore throat was the preceding infection in 60 per cent of the 1,200 rheumatic children studied; and respiratory infections are an important factor in recrudescences of rheumatic phenomena.

KAISER, A. D. Factors that Influence Rheumatic Disease in Children. *J.A.M.A.* 103, 12:886 (Sept. 22), 1934.

Do We Need Cancer Propaganda—Urging the need for better medical preparation for early diagnosis of cancer, the author minimizes the need for more lay education with the opinion that probably there are few individuals over twenty-one who have not heard about cancer.

MACCARTHY, W. C. The Cancer Problem Today. *J.A.M.A.* 103, 13:957 (Sept. 29), 1934.

Praise for Raw Milk—Copious evidence, almost amounting to proof, is at hand that raw milk taken by children and growing boys and girls acts as a preventive of dental caries: pasteurization of milk reduces its nutritive value; small doses of bovine tubercle bacilli protect against human type infection;

undulant fever from cows is uncommon anyway; streptococcic mastiditis has never been proved pathogenic to man; the cow is becoming too civilized an animal. These are the suggestions set forth by the Director of Dental Studies of the London Hospital.

SPAUSEN, E. Raw Milk and Sound Teeth. *Pub. Health*, 47, 12:388 (Sept.), 1934.

Dental Hygiene and Health—Providing free dental care for 9,400 poor children in New York, emphasizing preventive features, and training a large group of dental hygienists is the impressive record of the Guggenheim clinic for last year.

MCCALL, J. O. Dental Care as a Health Measure. *Child H. Bull.* 10, 5:158 (Sept.), 1934.

Strengthening Weak Spots in Nursing—How federal and state health authorities may contribute to improving the public health nursing services concludes this interesting discussion of the findings of a recent survey of public health nursing.

McIVER, P. Some Findings of the N.O.P.H.N. Survey of Public Health Nursing of Significance to State Health Administrators. *Pub. Health Rep.* 49, 37:1081 (Sept. 14), 1934.

Tests for Dangerous Dusts—Another paper revealing that the response of the peritoneal tissue to various dusts can be used as a test to determine the possible harmfulness of an industrial dust.

MILLER, J. W., *et al.* Response of Peritoneal Tissue to Dusts Introduced as Foreign Bodies. *J.A.M.A.* 103, 12:907 (Sept. 22), 1934.

Encephalitis Virus Transmitted Experimentally—Virus from the brain substance of persons dying during the St. Louis encephalitis outbreak can be carried through white mice; it is neutralized by convalescent serum but not by normal serum or convalescents from Japanese or Australian varieties of this disease.

MUCKENRUS, R. S., *et al.* Etiology of the 1933 Epidemic of Encephalitis. *J.A.M.A.* 103, 10:731 (Sept. 8), 1934.

Of Interest to Health Department Laboratories—Described in detail and well illustrated is the laboratory equipment developed in an attempt to improve existing sanitary engineering laboratories.

REDDICK, T. M. Some Developments in Sanitary Engineering Laboratory Equipment at New York University. *J. Am. W. W. Assn.* 26, 9:1238 (Sept.), 1934.

Child Hygiene Program Weaknesses—Current child health projects are scrutinized and the weaknesses are pointed out. The conclusion is that child hygiene is not an entity. State health departments should provide leadership in maternal and child health as a part of a whole community health promotion program.

WARNER, E. F. Child Health Activities in a State Department of Health. *Pub. Health Rep.* 49, 36:1056 (Sept. 7), 1934.

ASSOCIATION NEWS

SCIENTIFIC EXHIBITS IN PASADENA

THE best Scientific Exhibits which have ever been sponsored by the American Public Health Association were shown in the Exhibition Hall of the Civic Auditorium during the period of the 63rd Annual Meeting in Pasadena. Eighteen organizations participated, covering 3,000 square feet of space with exhibits of their valuable contributions to public health, ranging from the simplest of gadgets to make easier the work of the health department personnel, to the extensive exhibit imported from the Dresden Museum of Hygiene in Germany especially for this meeting.

There was also included in this exhibit Mr. Routzahn's well known education and publicity display. This needs no introduction or description for it has been an indispensable part of Association meetings in the past. Delegates never fail to attend it, and its popularity is, without doubt, well deserved.

The exhibit from the Dresden Museum of Hygiene dealt primarily with the subject of Eugenics. Although the subject matter was interesting, the exhibit was important principally as a demonstration of methods of presentation which have been developed to such a high degree by the Museum through many years of study. Pictures and models were used extensively. Printed material was conspicuous by its absence, the briefest of titles being used to explain the subject matter so adequately depicted in the photographs and models. A number of valuable suggestions in effective exhibit methods

were offered to those particularly interested in health education.

The delegates manifested great interest in the exhibit. It is planned to display this material in several cities throughout the country, which will give an additional number of health workers an opportunity to study it.

The gadget exhibit comprised contributions from several health departments, including the city and county of Charleston, S. C., the New York City Health Department, Buffalo Health Department, and the Los Angeles County Health Department. The exhibit was comprised chiefly of simple devices which have originated in the administrative offices or laboratories of these health departments and have been found useful and helpful in expediting their work. Typical examples of these gadgets are a convenient rack for baskets of test tubes, an inexpensive animal board, and a deep water sampling outfit. These gadgets were suggestive for the creation of many other similar devices to those who viewed them.

The exhibit of the City of Pasadena covered several phases of their work and included a three dimension model of the Morris Dam with a continuous flow of water over the spillway, pictures showing details of the activated sludge plant and the processing of fertilizer manufacture, an illuminated series illustrating the work of the Tumor Clinic, and a presentation of Pasadena's poliomyelitis control in 1934.

The California Tuberculosis Association included in its display an illumi-

nated frame showing X-ray pictures and a neon chart entered by the California Medical Association illustrating the reduction in the death rate from tuberculosis since 1906.

California was further represented in the exhibit by contributions from the State Board of Health, the George Williams Hooper Foundation, the Los Angeles County Health Department, and the Los Angeles City Health Department.

The State Board of Health included pictures and graphs showing the historical development of the Board, also plague demonstration material, demonstration of biologics prepared by the State Hygienic Laboratory, and a graph showing the history of plague in California.

The George Williams Hooper Foundation of the University of California had a graphic display of the epidemiology of brucella infections, relapsing fever, psittacosis, and rickettsia infections.

The Los Angeles County Health Department, the most unique county department in the United States, portrayed its work through a selected series of charts and photographs emphasizing particularly their health centers, medical social service, dental hygiene, and communicable disease control activities.

The Los Angeles City Health Department had a very realistic exhibit from its rodent control division showing the application of ratguards to ship mooring lines at the harbor, and demonstrating the impossibility for a rat to make its way to the dock. It included, also, a demonstration of the Palm Tree Rat Exterminating Truck. Rat extermination in palm trees being a problem unique in Southern California since, contrary to popular belief, the palm tree affords an almost perfect harborage for rats.

The ground squirrel poisoning method—by means of poisoned grain and car-

bon bisulphide gas—was demonstrated by constructing in detail a section typical of squirrel infested territory both the surface and the ground below, with material and equipment in action.

The Bureau of Housing and Sanitation, Milk Division, and Fruit and Vegetable Division were represented by various pictures, charts, and models of their work. Among the latter were two outstanding educational models; one—"The Perfect Restaurant"—a miniature of a restaurant showing all building features, fixtures, kitchen, dining room, and toilet arrangement as required by the city ordinances. The other—"A Model Refrigerator Car"—a perfect replica of the well known orange colored "Freaser Cars" employed in transporting fruit and vegetable products under ice or special ventilation.

The Medical Section of this Los Angeles City Exhibit included a model of a classroom of the Post Graduate Nurses' course in obstetrical procedure from the Nursing Division, a model of a Neo Salvarsan Clinic for the treatment of syphilis from the Women's Venereal Division, a bacteriologic laboratory exhibit of the poisonous "Black Widow" and common garden spiders, and an exhibit of charts from the Epidemiological and Quarantine Sections illustrating the behavior of the 52 diseases "Reportable" under the law of California.

In addition, wall maps and charts of the organization, were on display.

The Scientific Exhibits included two others of particular interest; one, on eugenic sterilization, summarizing a study of the 10,000 patients who have been sterilized in California during the past 25 years. The other, by the U. S. Public Health Service, illustrating by means of photographic transparencies the developmental cycle concerned in the application of mosquito salivary glands in malaria therapy. This method is designed to replace the transfusion of

blood and the use of live mosquitoes in the treatment of paresis. Used as a culture, the extracted glands have been kept alive for 21 days.

In addition to the inside exhibits, two motor units were shown on the plaza immediately adjacent to the Exhibition Hall. The Santa Barbara mobile dental unit is an automobile trailer with full dental equipment, including compressed gas for heating and sterilizing instruments, running water, and electric power from storage batteries. This is used for teaching and demonstrating hygiene of the mouth as practised in the schools of remote and mountainous districts. The second motor unit was the mobile squirrel dissection laboratory of the State Health Department.

Demonstrations of squirrel dissection were given daily and proved of great interest to many visitors.

The success of the Scientific Exhibits was in a considerable measure due to the splendid work of the Pasadena Committee and particular credit goes to Mr. Charles W. Arthur, Pasadena Health Department for his devoted and capable service in managing the exhibit and directing its installation.

The 64th Annual Meeting is looming ahead and the Committee on Scientific Exhibits is already looking forward to another Scientific Exhibit, at least comparable, if not better than that at Pasadena.

HOMER N. CALVER, *Chairman*
Committee on Scientific Exhibits

BROADCASTING AT A.P.H.A. MEETINGS

SEVERAL years ago it was decided to make use of the radio at our Annual Meetings for the broadcast of public health information. The matter was arranged by Dr. F. O. Tonney, Radio Adviser to the President's Committee on Radio of the A.P.H.A. At the recent meeting in Pasadena, 23 radio speakers were engaged, the names of which appear in our program of the meeting. There were 23 broadcasts made, of which 20 were over the Don Lee Broadcasting System on the Pacific Coast, with 13 to 16 stations reaching as far to the East as Denver. Three of them were on a National network of 50 stations, covering the central and eastern states. Dr. Tonney reports that many responses from the audience are coming in.

SOUTHERN BRANCH ANNUAL MEETING

THE Third Annual Meeting of the Southern Branch of the American Public Health Association will take place in San Antonio, Texas, on November 13 and 14, in conjunction with the Southern Medical Association,

which meets from November 13 to 16.

An excellent program of two morning sessions and two afternoon sessions has been arranged. Some of the subjects to be presented are: The Objectives and Possibilities of the Public Health Movement in the South, by A. T. McCormack, M.D.; Tuberculosis Control, by I. C. Riggins, M.D.; Tennessee Valley Authority, by E. L. Bishop, M.D.; Newer Approaches in Health Education, by Henry F. Vaughan, Dr.P.H.; The Use of the Untrained Nurse in Emergency Public Health Work, by Pearl McIver, R.N.; CWA-ERA Malaria Control Program in the South, by L. L. Williams, Jr., M.D.; Recent Sanitary Improvement Projects with Public Funds, by V. M. Ehlers, C.E.; Depression Effects on Typhoid Epidemics, by J. N. Baker, M.D.; The Efficacy of Typhoid Prophylaxis in the United States Army, by Robert U. Patterson, M.D.; The Efficacy of Typhoid Prophylaxis in the United States Navy, by S. S. Cook, M.D.; Some of the Public Health Problems in Texas and How They Are Being Met, by John W. Brown, M.D.; Diph-

theria Immunization, by A. H. Flickwir, M.D.; and The Prevailing Reduction in Public Health Budgets in Texas and What Is to Be Done About It, by J. W. Bass, M.D.

All southern health workers interested

in public health progress are invited to attend the meeting and participate in the discussions. For further information write to Dr. G. Foard McGinnes, Secretary, Southern Branch, State Department of Health, Richmond, Va.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Monroe F. Brown, M.D., Phm.D., Fayetteville, Tenn., Director, Lincoln Health Dept.
William R. Dorr, M.D., Arlington, Calif., Superintendent, Riverside County Hospital
Gordon Hastings, M.D., State Board of Health, Little Rock, Ark., Assistant State Health Officer
Thaddeus C. Kimble, M.D., Ph.D., Miltonvale, Kans., City Health Officer
William P. Lee, Huey Bldg., Cisco, Tex., City Health Officer
Aaron Leifer, M.D., 340 St. Johns Place, Brooklyn, N. Y., Medical Inspector, New York City Dept. of Health
Edward G. McGavran, M.D., Hillsdale, Mich., Director, Hillsdale County Health Dept.
Claud L. Murphree, M.D., Court House, Gadsden, Ala., Etowah County Health Officer
W. H. Smith, Box 216, Hondo, Tex., Medina County Health Officer
Samuel D. Sturkie, M.D., Oneonta, Ala., Blount County Health Officer

Laboratory Section

Kenneth L. Burdon, Ph.D., Washington University School of Medicine, St. Louis, Mo., Instructor in Bacteriology, Immunology, and Public Health

Public Health Engineering Section

Joe C. Behrens, B.S., 4300 Maypole Ave., Chicago, Ill., Sanitary Engineer, City Board of Health
John A. Clark, A.B., 141 Belleview Drive, San Leandro, Calif., Sanitary Engineering Inspector
Eugene F. Schad, B.S., 1046 N. Kedzie Ave., Chicago, Ill., Junior Assistant Sanitary Engineer

Public Health Nursing Section

Alice Austin, R.N., 681 Merrick, Detroit, Mich., Supervisor of Public Health Nurses
Frances A. Barringer, R.N., Court House, Charlotte, Va., County Health Nurse

Martha E. Booher, R.N., 820 Florida Ave., Blountsville, Tenn., Staff Nurse, Sullivan County Health Dept.

Claudia Davidson, R.N., 2902 Belmont Blvd., Nashville, Tenn., Field Nurse

Hazel Fees, Jamestown, Tenn., County Health Nurse

Jean E. Greer, R.N., 3317 White Bldg., Seattle, Wash., Director, Seattle Visiting Nurse Service

Ethel R. Jacobs, Albion, Ind., Noble County Public Health Nurse

Mrs. Pearl L. Maier, R.N., C.P.H., Gladwin, Mich., Public Health Nurse, Children's Fund of Michigan

Evelyn E. Morgan, R.N., Pike County Health Dept., McComb, Miss., Staff Nurse

Anne Pelley, R.N., Batesville, Ark., County Health Nurse

Industrial Hygiene Section

Leroy P. Kuhn, M.D., 4750 Sheridan Rd., Chicago, Ill. (Assoc.)

Food and Nutrition Section

Frederick B. Carter, El Monte, Calif., Manager, Arden Farms, Inc. (Assoc.)

Public Health Education Section

Thomas B. Kirkpatrick, M.A., University Hall, Columbia Univ., New York, N. Y., Teaching Community Hygiene

Epidemiology Section

John S. Cunningham, M.D., La Plata, Md., Deputy State and County Health Officer

Dale McCoy, D.O., Burlington, Kans., Coffey County Health Officer

Katherine A. Nye, M.D., 803 Lowry Medical Arts Bldg., St. Paul, Minn., Medical Inspector, Dept. of Health

Request for Change in Status

Maria W. Bates, 112 Linden Ave., Malden, Mass., formerly Associate Member, is now Health Teacher, Beebe Junior High School, Malden, Mass.

PASADENA SPECIAL

"ALL aboard!" At 9.15 on the evening of August 28, many fortunate members of the A.P.H.A. heard that call. It started the A.P.H.A. Special Train to the Pasadena meeting. Three sleepers left Grand Central Station on one of the most interesting itineraries many of the passengers have ever taken.

To all those aboard the same ideas probably came: Who is taking the trip? In what car are my friends? I wonder whether someone would like to play bridge? These questions were soon answered, and before the train reached Harmon, N. Y., groups had assembled to talk and to discuss matters important to them.

Early in the morning the train reached Buffalo. Some energetic spirits arose to see the station, but their number was not legion. At breakfast one of the most convenient of all arrangements made itself evident—All you had to do to get a delightful meal was to give up one of your tickets in the scrip book turned over to you with your ticket. Why, you could almost imagine that you were receiving a free meal! And, further, you were not troubled with any tipping. All those incidentals were included in the ticket. This scheme has great appeal to anyone who has traveled considerably. It surrounds you with the atmosphere of a private train.

About noon more members joined the Special at Detroit. These were greeted by friends and promptly initiated into the "family."

By now the travelers had settled down. Here you could see one of the Association officers working on a paper; in another section committee members were studying the year's work. These activities were noticed on the entire trip to Pasadena in spite of the scenery passed enroute and the enter-

tainment provided at stops. This speaks well for the diligence of many of our officers and members.

Arriving in Chicago about 5.30 p.m., we were met by Dr. Herman N. Bundesen and some of his staff. In taxicabs the entire party was promptly taken to the Century of Progress Exposition where, in Old Heidelberg, a satisfying dinner was served. This meal was made quite enjoyable by the music—vocal and instrumental—of the costume clad German singers. After dinner, one's time was his own until train departure at 1.00 a.m. Some of the party enjoyed the view from the Sky Ride; others went to see the fine displays of the automobile manufacturers; while it is said that many spent the entire evening in the Streets of Paris.

Leaving Chicago, our Special Train was complete with five sleepers, a diner, a club car, and an observation car. From this point on the train belonged to the A.P.H.A. There were now no "furriners" aboard, and the train officials made it clear that the party was to enjoy itself in the full freedom of the train. (It was reported that two of the party were in the engine when the train was standing at a station.)

From Chicago to the Mississippi River all slept, but bright and early that morning (Thursday) some witnessed the river crossing. At noon we were in Kansas City where a stop of 45 minutes afforded opportunity to see the beautiful station and the impressive war memorial across the plaza from the station.

Leaving Kansas City the route followed the old Santa Fe Trail, passing Newton, Kans., about 7.00 p.m., and Dodge City at bedtime. Early Friday morning the mountains started to fly by the windows. Early risers were well

rewarded by seeing the summit of Raton Range at Raton, N. M., a point 7,622 feet above sea level. About noon the train reached the Pueblo Indian village country. The villages, peculiar to these Indians, were intensely interesting.

At Albuquerque, the party had ample time to visit Fred Harvey's Museum and to rave over the interesting objects he has collected. The beaten silver jewelry with turquoise ornamentation was especially attractive to the ladies, and evidences of some purchases were seen on fingers and wrists after the train left.

On to Gallup! Here took place one of the events of the trip which made a lasting impression on all. The 12th Intertribal Ceremonies were being held and the A.P.H.A. party was privileged to see the last night of it. Many tribes took part, exhibiting such tribal dances as the Eagle Dance, the Crow Dance, and the Fire Dance. What a thrilling episode in the life of those unaccustomed to such exhibitions! The Indian audience watching the dances was just as intriguing as the dancers themselves.

Grand Canyon all day Saturday! This was another of the high spots of the trip. Adequate description is impossible—one must see it. A westward drive to Hermit's Rest occupied the morning. In the afternoon some took the trip to Indian Watch Tower which is to the east along the south rim. This is a beautiful drive and the Watch Tower one of the loveliest pieces of design and construction typifying the Pueblo Indian to be found anywhere. Five members of the party were hardy enough to descend the canyon to the river on muleback. Their tales of "heroism" after returning indicated an enjoyable trip. The Mojave Desert was crossed on Sunday morning. At San Bernardino the party was welcomed with customary California hospitality. A Spanish orchestra was playing at the

station; oranges were offered to quench one's thirst; and officials of the city and the Chamber of Commerce greeted the travelers personally.

After the cordial greeting at San Bernardino, the Special slipped into Pasadena, where the Local Committee, headed by Dr. Dunshee, welcomed the group of more than 100 and saw to it that each was happily settled for the busy convention ahead.

After the Annual Meeting—a busy and successful one—all were loath to leave. But, after all, the Special did have to depart on schedule and, except for a small party which was able to go to Yosemite National Park through the courtesy of some of the California State Department of Health officials, all were on board Thursday at departure time.

Would the return trip be an interesting one?—This thought occurred to many as they boarded the train. It was needless. The return trip, somewhat like Grand Canyon, cannot be adequately detailed or described. At San Francisco Dr. Geiger was a delightful host; at Stockton and Lodi, Dr. Sippy justified his reputation for entertaining; and at Sacramento Dr. True displayed the true California spirit of hospitality. In all of these four interesting areas instructive and entertaining programs requiring the constant attention of the entire party had been planned and were executed with precision and with pleasure to the participants.

It was only with regrets that the members of the party left California. All of the western members as well as the associations affiliated with the parent organization, fully justified the expectations of the "swell" time forecast for the meeting.

Sunday, after leaving Sacramento, was replete with scenery. Here the mountains, snow-capped because of a recent snowfall; there the flat country and the famous Salt Lake, over which the train travelled for miles. The con-

trast of mountains, flats, and blue water is such as to leave a vivid impression on one's memory.

At Salt Lake City, Dr. Beatty met the Special. A well planned stop-over included a tour of this lovely city situated in the bottom of a natural bowl, a visit to the Tabernacle of the Latter Day Saints, where a special organ recital was given and a dinner under the auspices of the Chamber of Commerce. The thoughts of the individual members of the party will always deal kindly with Salt Lake City, and the gracious residents of that city.

From Salt Lake City to Denver the route displayed some of the most spectacular scenery in America. The Fraser River Canyon, along the Colorado River, up into and through the Moffat Tunnel—all these produced wonderful and characteristic views long to be remembered. Obviously this lovely scenery could not go on interminably. The Special arrived in Denver early Monday afternoon, where Dr. Jaffa and Dr. Beaghler greeted the travelers, promptly arranged for their

comfortable transportation to Lookout Mountain, and engineered the last lovely tour of the trip. From the consecrated spot hallowed by the grave of Buffalo Bill, an inspiring view of Golden and of Denver, far in the background, was had. From this vantage point the group twisted and turned down the Lariat Trail, back to Denver and a most welcome and enjoyable dinner.

Knowing that Denver was the last stop-over of the Special Train, the footsteps of the passengers seemed to lag on the way through the station. But after kindly farewells and promises to return, the train moved out, seeking New York, its destination. From Denver to New York was uneventful except for the conversations of the Special party in which the pleasures of the entire trip were discussed and rehearsed from person to person.

All good things must end, and New York saw the close of one of the pleasantest and best planned trips in the Association's history.

"Here Porter, please take my bags."

NEWS FROM THE FIELD

DELEGATES TO ARGENTINA CONFERENCE

KENDALL EMERSON, M.D., Life Member and Executive Secretary of the A.P.H.A., and Managing Director of the National Tuberculosis Association, will be one of the delegates representing the United States at the Pan-American Sanitary Conference in Buenos Aires, Argentina, November 12-22.

Surgeon-General Hugh S. Cumming, F.A.P.H.A., and B. J. Lloyd, M.D., member A.P.H.A., of the U. S. Public Health Service, will be the other delegates, Dr. Cumming acting as chairman of the delegation. They sailed from New York on October 13.

NATIONAL ADVISORY COUNCIL ON RADIO IN EDUCATION ENTERS PUBLIC HEALTH FIELD

THERE will be 19 programs of 15 minutes each (10:45-11:00 Eastern Standard Time) every Monday evening, from October 2 through February 25—excepting October 27, November 5, and November 12—over a nation-wide network of the Columbia Broadcasting System.

This series of broadcasts will consider the subject of medical economics, the cost of medical care, the relation between the medical profession and the public, and ways of reconciling the interests of the two groups.

All the programs will be published by the University of Chicago Press, 5750 Ellis Avenue, Chicago, and each program will be available shortly after it is broadcast, for \$.15 for individual numbers, or \$2 for the series of 19.

The Public Health Committee of the National Advisory Council on Radio in Education is headed by William Trufant Foster, Director of the Pollak Founda-

tion, and includes Dr. Haven Emerson, Dr. Alice Hamilton, Dr. Thomas Parran, Jr., Dr. H. S. Cumming, and Dr. Ray Lyman Wilbur. The National Advisory Council on Radio in Education is headed by Robert A. Millikan as President, and Levering Tyson is the Director.

JANUARY 1933 JOURNALS WANTED

READERS of The American Journal of Public Health are asked to send spare copies of the January, 1933, issue to the American Public Health Association, 50 West 50th Street, New York, N. Y., as this issue is out of stock. This will be much appreciated, and reimbursement of postage will be made in each case.

A.S.H.A. WITHDRAWS SPONSORSHIP OF FILM

THE American Social Hygiene Association announces withdrawal of sponsorship of "Damaged Lives," the commercially produced motion picture film they undertook to sponsor a year ago. The Weldon Pictures Corporation, who are the owners of the film, have been asked to remove from the film and all prints thereof and from all advertising, pamphlets, or other material used in connection with future showings, the name of the A.S.H.A. as sponsors.

This action was taken not because of a change in viewpoint as to the value of the film, but because "it has apparently proved impossible for the Weldon Pictures Corporation with its limited organization and commercial affiliations to control undesirable and unauthorized activities of distributors and exhibitors in the local advertising and showings of the films."

HEALTH COUNCIL ESTABLISHED

THE District of Columbia Health and Hospital Council, composed of representatives of medical, dental and civic societies, was recently formed, sponsored by the Council of Social Agencies.

The council will be available to all government authority as a medium of ascertaining opinion and reaction of the majority in professional, administrative and lay organizations representing the citizens in the district, it is stated.

CALIFORNIA A.W.W.A. CONVENTION HELD

THE California Section of the American Water Works Association held its 1934 Convention at Long Beach, Calif., October 24-27.

PERSONALS

PAUL F. RUSSELL, M.D., member A.P.H.A., of the Bureau of Science in Manila, P. I., announces that he has been assigned to work in India, at Kasauli, Punjab. His mail address, for the present, is the All-India Institute of Hygiene, 21 Central Avenue, Calcutta, India.

DR. JOSEPH C. KNOX, Assistant Epidemiologist of the North Carolina State Board of Health, Raleigh, N. C., has been appointed Epidemiologist, succeeding Dr. Daniel F. Milam, member A.P.H.A., who has been transferred to Panama by the International Health Board of the Rockefeller Foundation. He was assigned as consulting epidemiologist to North Carolina 2 years ago. Dr. Robert E. Fox, member A.P.H.A., of Boston, formerly Health Officer of Buncombe County, has been made Assistant Director of County Health Work.

DR. NOLTON N. ASHLEY has been appointed Health Officer of Oakland, Calif., succeeding Arthur Hieronymus, M.D., member A.P.H.A.

DR. STANLEY R. PARKINSON, of Marysville, Calif., has succeeded Dr. James

H. Barr as Health Officer of Yuba County.

DR. DENVER D. ROOS has been appointed Health Officer of Corona, Calif., following the retirement of Dr. William S. Davis.

JACOB J. GOLUB, M.D., member A.P.H.A., sailed for Europe July 5 on his way to spend 2 months as consultant to the Hebrew University in Palestine in connection with the building of the Hebrew University Hospital in Jerusalem.

JOHN O. McREYNOLDS, M.D., associate member A.P.H.A., of Dallas, Tex., recently had the Venezuelan medal of honor conferred on him in recognition of his services to the cause of education "as a mark of the gratitude of the people of Venezuela."

WARREN F. DRAPER, M.D., F.A.P.H.A., of Richmond, Va., Assistant Surgeon General of the U. S. Public Health Service, resigned, and will be succeeded by Dr. J. C. Riggan, F.A.P.H.A., also of Richmond.

Previous History of Poliomyelitis in California*

J. D. DUNSHEE, M.D., F.A.P.H.A., AND I. M. STEVENS, F.A.P.H.A.

Director, and Supervising Morbidity Statistician, State Department of Public Health, San Francisco, Calif.

ACUTE anterior poliomyelitis has occurred in California for many years. Gundrum¹ obtained an accurate account of a case which had developed in Eureka in 1875. This case was in a child aged 2 years with an acute onset "followed in a few days with paralysis in the lower extremities," and the patient stated that another child had developed a similar illness "at about the same time." Gundrum reported further that a careful check of the medical literature failed to reveal any indication of subsequent cases until 1896, although in 1913 he² reported that his investigation had been continued and he had obtained data regarding 2 cases near Bodega Bay, Marin County, in 1888.

Sherman³ in 1897 stated:

It is now over 12 years since I treated a child for indigestion who had a poliomyelitis, and since that time I have never seen a child in whose case the diagnosis was obscure without examining to see if the child could move all its extremities. I have not yet found my second case, but last summer I got to within

2 weeks of the invasion and sometime, if I live long enough, I will make the diagnosis.

During 1896, 8 cases were brought to his attention—7 in San Francisco and 1 in Napa.

Two years later, 1899, Newmark⁴ published his observations: "A Little Epidemic of Poliomyelitis," presenting 4 cases which had occurred in 1898 in Merced County. Three of the cases were in the town of La Grande having only 49 inhabitants, and the 4th was in the outlying district about 3 miles from town. Sawyer⁵ in commenting on the incidence of poliomyelitis in Humboldt County mentioned 1 case at Field's Landing during 1898.

Woods⁶ reported:

During this year (1901) the infection that causes acute anterior poliomyelitis was very lively in this state, it being most active, however, during the months of May and June. The little victims are to be found among all classes, the entire length of the state; at the seaboard towns, as well as in the interior; in the mountain districts, and again from the valleys. By far, the greater proportion was in San Francisco and its immediate vicinity.

Detailed histories of 25 cases were given and reference was made to 30 additional

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

cases in children. The author referred also to several children stricken in San Francisco in 1902. Brown⁷ reported cases in Watsonville and vicinity, Santa Cruz County in 1907, and in Redding and Red Bluff in the northern part of the state during 1909. Sawyer⁵ mentioned 1 case at Samoa, Humboldt County, in 1908.

No additional references to case reports for California prior to 1910, have been found. The morbidity and mortality records for that period as published by the California State Board of Health did not include any reference to the incidence even for the years during which poliomyelitis was known to have occurred, and it was not until 1912 that the term "acute anterior poliomyelitis" was listed as a cause of death. However the U. S. Bureau of the Census first tabulated acute poliomyelitis deaths separately in 1909. Lavinder, Freeman and Frost⁸ in their tabulation of reported deaths and cases for the United States by states credited California with 12 deaths from this infection in 1909 and referred to 67 cases reported by Fleischer.

We are indebted to Dr. F. F. Gundrum of Sacramento for detailed accounts of the prevalence of this disease throughout California during 1910, 1911, and 1912.^{1, 2, 3} The State Board of Health¹⁰ in 1910 detailed him to conduct an official investigation throughout the state. During the same year, the San Francisco County Medical Society appointed a committee for the study of "anterior poliomyelitis" in San Francisco. The report of this committee was compiled and submitted by Fleischer.¹¹

It is interesting to note that all of the above references pertain to cases occurring north of Tehachapi. With the exception of Woods's⁶ statement that cases occurred over full length of the state, one would infer that no outbreak had been observed in Southern Cali-

fornia prior to 1912 when Orbison¹² presented a report on epidemic poliomyelitis in Los Angeles. He stated that during the week ending June 15, 1 case was reported to the health officer, and during the following 4 weeks 77 cases were recorded. Then at the request of the City Health Commissioner a meeting of "physicians, clergymen, laymen, and women" was called on July 19 and as a result a committee was appointed to serve as an advisory board with the Health Commissioner. For the period June 15 to August 27, 1912, 239 cases were officially reported.

The incidence of poliomyelitis in California from 1909 to date as assembled by the State Department of Public Health is shown in Table I.

TABLE I

Year	Cases	Deaths
1909.....	67	12
1910.....	139	29
1911.....	55	13
1912.....	531	129
1913.....	90	33
1914.....	56	27
1915.....	62	19
1916.....	145	24
1917.....	67	26
1918.....	69	20
1919.....	27	9
1920.....	75	30
1921.....	283	49
1922.....	62	24
1923.....	251	33
1924.....	192	34
1925.....	821	144
1926.....	187	30
1927.....	1,298	224
1928.....	303	80
1929.....	171	46
1930.....	1,903	157
1931.....	293	48
1932.....	191	31
1933.....	170	14
1934 (to Aug. 18th)	2,648	64
		(Jan. through July)

We may say that during this period there have been 5 extensive epidemics (see Table II).

TABLE II

	<i>Reported Cases</i>	<i>Deaths</i>
1912.....	531	129
1925.....	821	144
1927.....	1,298	224
1930.....	1,903	157
1934 (to Aug. 18) ..	2,648	64
		(through July)

There was a lapse of 13 years between the first and second epidemics and the last 4 have taken place during the past 9 years at 2, 3, and 4 year intervals. Certainly no regularity of epidemic cycles is apparent.

It is difficult to compare the types of infection in the different epidemics. The basis of diagnosis has varied and also the definition of reportable cases has changed. However, the death rates have confirmed our observation that the 1912 and the 1927 outbreaks were the most severe. The consensus of opinion from the data available at present is that the cases have been mild this year even though the total number of cases greatly exceeds those of any previous year.

In plotting the incidence for each year by months, the peak has usually fallen within the months of July to October; however, in 1896, 1901, and 1934, the highest incidence appeared in June. The records for 1896 are not representative of the state as a whole because only those cases reported by San Francisco physicians are available. In 1901 Woods⁶ referred to a state-

wide epidemic and stated that poliomyelitis was most active during the months of May and June. At no time since 1901, even in any one population center, has the highest incidence appeared as early as May and June until 1934. Observations on the seasonal incidence of poliomyelitis in California to date, indicate conclusively that a consistent increase during March and April is the forerunner of a summer epidemic.

Regarding age distribution, the available data present evidence of a definite shifting of the incidence of this disease in California to the older age groups. Once again the definition of what constitutes a reportable case may be a factor. With better diagnosis more cases among adolescents and adults may be detected. Even assuming that these factors may have played a part in this shifting of age distribution, the fact remains that the percentage of cases among young children has so definitely decreased in favor of the older groups that we feel this trend, observed by Forsbeck and Luther of Massachusetts, Knowlton of Connecticut, and Frost and Das and others,¹³ applies to California also. Gundrum² reported that during 1910-1912, 363, or 72 per cent of the 706 recorded cases, were under 8 years of age. During 1932-1934, 1,253, or 46 per cent of the 2,697 reported cases, were under 10 years of age. An analysis of the 5 epidemics (see Table III) shows the age distribution.

TABLE III

<i>Year</i>	<i>Cases Under 10</i>		<i>Cases Over 10</i>		<i>Total *</i>
	<i>Years of Age</i>	<i>Per Cent</i>	<i>Years of Age</i>	<i>Per Cent</i>	
1912.....	277 †	78.0	254	22.0	531
1925.....	533	65.7	279	34.3	812
1927.....	803	62.9	475	37.1	1,278
1930.....	1,112	59.4	764	40.6	1,876
1934.....	1,034	44.1	1,309	55.9	2,343

(to Aug. 1st)

* Total number of cases with ages specified

† Only available data state cases under 8 years of age instead of under 10 years

During each of these epidemic years there has been a consistent decrease from 78 per cent under 8 years to 44 per cent under 10 years. A more detailed analysis of this shift will be published when all of the data for 1934 have been compiled.

SUMMARY

1. Poliomyelitis is known to have occurred in California since 1875.

2. No data are available to indicate that this infection appeared in Southern California in epidemic form prior to 1912.

3. Records of 5 epidemics, 1912, 1925, 1927, 1930, and 1934, indicate that the June peak in 1934 is unusual.

4. There has been a consistent shifting of the age incidence to the older groups—in 1912, 78 per cent of the

cases were under 8 years of age; in 1934, only 44 per cent were under 10 years of age.

Measuring Health

. . . Further, it is contended that, in any case, the study of sickness and mortality, and reports thereon, does not represent *health* but disease.

On this last point, which is a cardinal one, it may be said at once that the only way in which it is possible to measure the health of a people, currently and concretely, year by year, is to gauge its degree by recording any departure from health as represented in sickness, incapacity or mortality. For the health of the individual is a physiological balance, an imponderable, subjective and objective, and the disturbance of its happy equipoise is the only indication of ill-health. If that ill-health be smaller or greater, or if our days be

curtailed or prolonged, we can deduce a standard of health. It may be a variable deduction, or even an "unscientific" one—that is inexact and relative only—but there is no alternative method to measure a nation's health apart from a complete periodic assize of the physique of the individuals composing the population—an impossible and fantastic task. Hence we must content ourselves with estimating our own health, or that of the nation by the evidence of the absence or presence, of dis-ease, incapacity or death. . . .
—Extract from the *Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1933*, p. 252.

Poliomyelitis, 1934*

J. L. POMEROY, M.D., F.A.P.H.A., AND
GEORGE H. ROTH, M.D., F.A.P.H.A.

County Health Officer, and Epidemiologist, Los Angeles County, Los Angeles, Calif.

SINCE the first of this year poliomyelitis incidence has been above seasonal expectancy, by May 1 there having been 61 cases as against 20 for the corresponding period in 1933. We had been calling attention to this increase and the necessity for early diagnosis and isolation in our weekly bulletin, the *Health Index*. We also announced to the profession the fact that we maintained a limited supply of convalescent poliomyelitis serum, and the necessity of the early administration if results were to be expected. As poliomyelitis has been appearing in California in waves about every 4 years since 1912, the last wave or epidemic having been in 1930, we were apprehensive that the disease was running true to form and that we were facing another epidemic.

The County Health Officer early in May called a meeting with our 12 District Health Officers, and ways and means of combating an epidemic were discussed. The County Health Officer at that time declared his intention of bringing into being a Poliomyelitis Advisory Board whose duties would be to advise with him and determine policies and control measures in a broad way. Accordingly a letter was addressed to a group of the leading physicians of the Los Angeles County Medical Association, who responded to the call, and the

organization was effected on May 14, 1934, with the Chairman of Public Relations Committee of the Los Angeles County Medical Association as President and the Chief of Staff of the California Babies' Hospital as Secretary. Other members were Chief of Staff of the Communicable Disease Division of the County General Hospital and his assistant, Chief of Neurological Service Children's Hospital, Health Officer of Pasadena, Director of Health Service of Los Angeles City Schools, Chief of Staff of the Orthopedic Hospital, Los Angeles City Health Officer and his Epidemiologist, Los Angeles County Health Officer and his Epidemiologist, Professor of Medicine of University of Southern California, Director of California Department of Public Health and his Senior Epidemiologist.

The following program was decided upon and carried out:

1. Bulletin, *What You Should Know about Poliomyelitis* for the lay public. One hundred thousand of these were distributed through the Parent-Teachers Association and various other agencies.
2. Bulletin to be issued by California State Department of Public Health and distributed to all physicians.
3. Circular letter to physicians of this county on symptoms and necessity for early diagnosis and treatment with pooled convalescent serum, the use of which was recommended by the board.
4. Continuation of schools as in normal years with additional provisions for daily medical inspection of all children and prompt isolation and reporting of all showing symptoms suggestive of poliomyelitis.
5. Continuation of regulated swimming with

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

special supervision and instructions relative to the danger of diving and ducking and otherwise washing the protective coating from the nasal mucosa.

6. Passage of a County Camp Ordinance with special provisions for medical inspection before entrance and daily medical inspection thereafter, also provisions for isolation of suspects.

It is noteworthy that not a single case of poliomyelitis developed in any of the camps so supervised.

A policy of taking the public into our confidence and keeping them properly informed of the exact status of the epidemic was agreed upon and followed to our entire satisfaction throughout the course of the outbreak. This was accomplished through the press and over the radio and seemed to be greatly appreciated by the public in general, as expressed editorially by a number of our metropolitan newspapers and by many private communications.

As the epidemic developed it became mandatory that additional funds be provided for diagnostic service, orthopedic service, and various other necessary functions. This request to our Board of Supervisors met with immediate response, so we were enabled to employ the necessary assistance to complete our program.

The matter of providing convalescent serum was a critical one owing to the sharp rise in incidence during the first weeks of May. The Chief of Staff of the Orthopedic Hospital called in a group of convalescents and provided the blood, and the Los Angeles County Health Department Laboratory prepared the serum, in all about 15 gallons. This afforded the chief supply for the General Hospital (the only contagious disease hospital in this county), and made possible the administration of serum from the beginning of the epidemic.

The necessity for early diagnosis and hospitalization was stressed from the beginning, especially in our more con-

gested areas where economic conditions were poor, as it was felt that such procedure would be productive of the best results. This is particularly true in our Belvedere District where the case rate was 1 to 400 population.

Through our policy of keeping the public informed, parents, instead of becoming panicky, would call their family physician, or a health officer in the event they could not secure a private physician, upon the appearance of first symptoms suggestive of poliomyelitis. Consequently, a large majority of our cases were discovered in the preparalytic stage and fully 90 per cent were hospitalized where serum and proper orthopedic care were administered. Those not hospitalized were provided with serum in the homes.

When cases or suspected cases were reported to our health centers a trained diagnostician responded to the call, made thorough examination, epidemiological investigation, and sent the patient to the hospital when indicated.

A trained nurse or physician checked contacts regularly for secondary cases, and also maintained a specially prepared chart in each quarantined home upon which were recorded all minor illnesses. Before releasing quarantine, an inspection was made by a physician and muscle check was made when the patient was in the home. All convalescent patients were routinely muscle checked at regular intervals after release from quarantine and in a few instances "straggling" cases of paresis were detected that had developed subsequent to release.

Our total incidence for the epidemic was 630 with a case fatality rate of $1\frac{1}{2}$ per cent.

In a careful history check of 370 cases we find the following:

1. Of 235 cases which received serum in the preparalytic stage in dosage from 50 to 100 c.c. on the 1st to 3rd day from onset, 213 or 90 per cent proved on muscle check after re-

lease from the hospital to be normal, while 22, or 10 per cent, showed weakness of certain muscle groups.

2. Of 100 paretic cases muscle checked after release from the hospital, 53 per cent showed no extension, 35 per cent showed complete recovery, and 12 per cent showed extension to other muscle groups but not to the extent of causing physical disability. Under present orthopedic treatment the prognosis is regarded as favorable for complete recovery.

3. Thirty-five were found in the muscle check to come in the paralytic class. Twenty-five of these had received serum very late, that is, from the 5th to 12th day from appearance of paresis. Ten were either missed or

refused serum. Our worst cases and the only ones in which we found "Trace or Gone" muscles were in this last group.

In conclusion, we feel that the extremely low case fatality rate and the small percentage of residual paralysis may to a certain extent be credited to three factors: (1) Early diagnosis, (2) early hospitalization and administration of pooled convalescent serum in full dosage, (3) proper orthopedic care while in the hospital and adequate provision for treatment after release.

Syracuse, N. Y., Continues Its High Standard of Health

DESPITE the fact that the budget was again cut, Syracuse, N. Y., reports in 1933 the lowest general mortality rate in the city's history, 10.9; and also established a new low rate for infant mortality, 39.6. For the forty-fifth consecutive year, there was no death from smallpox; there were only 6 local cases and no deaths from diphtheria; while the 4 typhoid fever deaths give a rate of less than 2 per 100,000.

With a birth rate of 16.1 a high average of hospitalization was maintained, 80 per cent of all births taking place in hospitals and 98.9 being attended by physicians. The tuberculosis death rate, 37.4, was a slight rise over the previous year.

As the health commissioner points out, only the facts that 1933 was singularly free from any major outbreaks of acute communicable disease and that supplementary personnel were contrib-

uted by government relief agencies made it possible for Syracuse to continue its high standard of health achievement.

The organization of prenatal and obstetrical service is of interest. There are 7 prenatal clinic sessions per week in the city, but not established as a separate bureau of the Department of Health. Health Department nurses are assigned to each of the clinic stations, and field supervision of the prenatal cases registered in the clinics is a responsibility of the district nurses' program. Medical supervision in the clinics is provided through the Syracuse University Medical School.

Where confinement is within the home, delivery and post-partum services are rendered through the clinic medical staff and the local Visiting Nurse Association, a stipulated charge for this home service being made to the Department of Public Welfare.

Epidemiology of Poliomyelitis in California, 1934*

JAMES P. LEAKE, M.D., E. T. CEDAR, M.D., W. PALMER
DEARING, M.D., ALEXANDER G. GILLIAM, M.D.

*Senior Surgeon; Passed Assistant Surgeon; Assistant Surgeon; and Assistant
Surgeon, U. S. Public Health Service, Washington, D. C.*

AND

HAROLD D. CHOPE, M.D.,

Assistant Director of Public Health, State of California, San Francisco, Calif.

UP to a year ago there had been no noteworthy increase of poliomyelitis in California since the last outbreak, that of 1930. Late in the fall of 1933 and during the following winter there was an unusual prevalence for that season of the year, presaging the 1934 epidemic. This prevalence was most marked in the counties nearest to Los Angeles County on the east and south; it is usually the southern part of the state which is first affected in epidemic years. As in other localities when poliomyelitis becomes prevalent, the interval from the previous outbreak gives some indication of the intensity to be expected. These intervals had been increasing in California—2 years between 1925 and 1927, 3 years between 1927 and 1930, and 4 years since the last outbreak, in 1930.

Epidemiological studies of the 1934 epidemic were undertaken by the U. S. Public Health Service and the California State Department of Health, with the coöperation of county and city health departments, and are at present being

carried on in the 4 centers of high incidence. These 4 centers, in chronological order of the appearance of the epidemic, are: Orange County, adjacent to Los Angeles on the south; Los Angeles County; the Bay region, comprising the counties of San Francisco, Alameda, Contra Costa, Marin, Napa, San Mateo, Santa Clara, Solano, and Sonoma; and Fresno County, which is located in the south-central part of the state in the San Joaquin Valley.

As regards the season of its beginning, maximum, and subsidence, this epidemic has been remarkably early, though not unique in this respect. In the equable climate of the Pacific Coast the seasonal occurrence of poliomyelitis might be expected to be, and is in fact, broader than for the United States as a whole. The curve of average incidence usually begins to rise in May, is high by July in the southern part of the state, but reaches a peak in September, somewhat later and less sharp than that for the entire country. As a basis for judging intensity of prevalence in the United States, except for the Southern States, it is convenient to consider 10 paralytic cases per 100,000 per year as a

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

"normal" rate or average rate of all such cases reported, with 1 case every 2 weeks for a population of that size during the peak of the season. In the largest epidemic in history, that of New York City in 1916, the rate was approximately 20 times this height; in 1931 about 10 times. In 1916, the reported cases were, in general, frankly paralytic. In later years the diagnosis has come to be made more and more without evidence of paralysis. The case fatality, based on reported cases, in the 1916 epidemic was about 24 per cent; in 1931 about 12 per cent.

At the time of writing, Orange County has reported 40 cases, a rate of 35 per 100,000 population, with 1 death. This case rate is only about $3\frac{1}{2}$ times the normal, and the occurrence of 1 death in 40 cases would correspond to a fatality of about 2.5 per cent. Consistent localization of poliomyelitis began in Orange County the second week of April. The peak of the outbreak, by onsets, was in May and early June, and the peak and subsidence have been earlier here than elsewhere in the state.

In Los Angeles city and county, the cases were widely scattered geographically, except for a sharp focus in May in the Ruth Protective Home, an institution for infants, children, and young women, located about 3 miles east of the city limits. The incidence of the disease in proportion to the population was remarkably uniform in the 16 assembly districts into which the city was divided, the heaviest incidence being in the most thinly populated district, the San Fernando Valley, and the next heaviest in two of the most thickly populated districts. One of the most thickly populated sections of the county outside the city, Belvedere, has had the heaviest incidence of the whole metropolitan area. The peak of the Los Angeles epidemic, in terms of onsets, was in the first week of June, and the subsidence since then has been generally

consistent, though gradual. The weekly rate was 10 cases per 100,000 at the peak, declining to $2\frac{1}{2}$ cases per 100,000 in the first week of August.

The outbreak in the San Francisco Bay region was sharper and less intense as regards the number of reported cases, than in Southern California. The Bay outbreak had hardly begun in mid-May, when the rate was less than one-tenth of the rate of the Los Angeles area at that time. At the peak, in mid-June, the rate for the Bay had risen to half that of the Los Angeles peak, which occurred 2 weeks earlier. The subsidence of the outbreak was also much more prompt around the Bay, the rate being normal for the season by August 10.

In Fresno, there was not 1 case per week until the middle of June. Since then the incidence in proportion to population has exceeded that in the southern part of the state, the peak by onsets occurring the first of July.

This epidemic has shown peculiarities which have raised questions of interest. One of the most prominent of the latter is that of the occurrence of atypical cases which, in the present paper, are included among the reported cases. Is it correct so to include them? Has there been more than one epidemic disease present? Some of the circumstances of this outbreak may shed light on this question. Mildness has characterized the disease in each of the four foci studied. While it is too early, and the deaths are too few, to emphasize case fatality rates, these have all been remarkably low—6.8 per cent in San Francisco, 2.5 per cent in Orange County, 2.3 per cent in Fresno County, and 1.5 per cent in Los Angeles County. All rates stated for this epidemic are based on all reported cases. However, even if only paralytic cases were considered, the above fatality rates would be remarkably low. Two-thirds of the cases in San Francisco have been

investigated, 63 per cent of these being paralytic. In the Los Angeles area 50 per cent of those investigated were considered paralytic, in Fresno—47 per cent, and in Orange County—57 per cent. Tending also to support the idea that the epidemic as reported is composed of not more than one disease entity is the fact that the atypical cases, relatively mild as regards paralysis, have been reported from various parts of the state roughly in proportion to the occurrence of the frank paralytic poliomyelitis.

Certain peculiarities in age and sex distribution are shown in Table I.

TABLE I
Percentage Distribution

<i>Age</i>	<i>Orange County</i>	<i>Los Angeles County</i>	<i>San Francisco Bay Communities</i>	<i>Fresno County</i>
Under 5 years	23	16		
5 to 9	28	28	12	17
10 to 14	28	19	28	24
15 to 19	13	8	27	23
Males, 20 and over	0	11	12	16
Females, 20 and over	8	18	9	6
		12		14
Total	100	100	100	100

Although in recent years poliomyelitis has shown less and less selectivity for the youngest age group, the above age distribution, especially as regards adults, is unusual in a population as urban as that involved in this epidemic. In spite of a marked predominance of adults among those whose attacks were atypical, the above age-sex distribution, with relatively high prevalence in adult females as compared with adult males, follows the expected incidence of an infectious disease transmitted by contact with the age group having the more typical cases, namely, the children.

The communicability of the disease in this epidemic was high. This is indicated by its unique incidence among hospital and nursing personnel, discussed elsewhere, and also by the fact that 12.5 per cent of the households so far tabulated with regard to this item,

had multiple cases. This is an unusually high multiple case rate for this disease in communities largely urban.

As commonly observed in poliomyelitis, the distribution of the cases as to milk supply and water supply has given no indication that either of these could have been a major factor in the spread of the disease in foci thus far studied. One advantage which we have had in the survey is the investigation of supposedly uninfected households as controls. The comparison with controls did not indicate any special peculiarity of the cases of poliomyelitis regarding milk or water supply. For the Los

Angeles area these control studies have also tended to exclude the often suspected swimming pools and beaches as primarily important centers for dissemination of infection; 12 per cent of the poliomyelitis patients and 15 per cent of the controls had indulged in this sport. On the other hand, approximately 8 per cent of the patients remembered unusual physical exertion immediately preceding the attack, while only 2 per cent of the controls gave such a history during a corresponding period immediately before the peak of the epidemic.

All the evidence at hand indicates that the mode of spread in this epidemic is similar to that which is usually accepted for poliomyelitis, namely, by contact with human carriers, and to a much less extent, with recognized cases of the disease.

1934 Epidemic of Poliomyelitis in Los Angeles*

Preliminary Report on the Pathological Changes in the Nervous System

ROY VAN WART, M.D., CYRIL COURVILLE, M.D.,
AND E. M. HALL, M.D.

*Professor of Neuropathology, University of Southern California; Professor of
Neurology, College of Medical Evangelists; and Professor of Pathology,
University of Southern California, Los Angeles, Calif.*

THE variable clinical manifestations of the cases occurring in this epidemic add to the interest in the changes in the nervous system which accompanied them. The large amount of material gave an excellent opportunity for their study. Fifteen cases came to autopsy in the Los Angeles County General Hospital, 11 of which have been summarized on the accompanying chart. Two cases were not included as complete material was not available. A third was complicated by a large cerebellar hemorrhage. All 3 cases showed extensive perivascular infiltration ("cuffing") of the vessels of the pons and medulla. Two showed no lesions in the spinal cord other than hyperemia. Intense perivascular infiltration of the vessels of the spinal cord was present in the third, not comparable to the slight cell destruction.

Dr. Kessel informs us that material from 5 of the 12 cases was successfully inoculated into monkeys. Two others produced atypical results.

Sections from the spinal cord of the typical cases which have been studied showed lesions similar to those found in the human cases. The lesions in the positive human cases did not differ from those in which the inoculation was unsuccessful. The human lesions in 1 successful animal inoculation were comparatively slight.

The gross appearance of the brain and spinal cord in all cases showed a marked hyperemia of the meninges. The underlying nervous grey and white matter was intensely congested and in several cases cyanotic. Sections showed the same hyperemia. Cross-sections of the spinal cord showed numerous minute hemorrhages in the grey matter.

The microscopic changes were most marked in the medulla, pons, and spinal cord.

The membranes covering these parts showed a variable amount of round cell infiltration. This was most marked around the blood vessels, and though it was usually present at that point, nowhere was it of the degree seen in a moderate meningitis.

The blood vessels throughout the nervous system were distended with red

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

blood cells. This was present equally in the grey and white matter. In the anterior horns of the spinal cord and in the medulla there were occasional minute capillary hemorrhages. The most characteristic change was the infiltration of the blood vessel walls. This varied from a few round cells to a complete ring. In more advanced cases the perivascular spaces and surrounding tissue were packed with cells. All degrees were seen in the same case and in a single section normal vessels were found alongside of those with more or less infiltration.

The more marked degree resembled the cuffing seen in encephalitis. The different levels of the cord showed great variation. Some sections showed every vessel involved, while in others it was limited to the vessels of the anterior fissure and the anterior horns.

Often the two halves of the cord showed different lesions, perivascular change on one side and nerve cell destruction on the other. This infiltration was often present alongside normal cells.

Irregular clumps of cells were found scattered through the grey and white matter of the cerebrum and cerebellum and more frequently in the pons, medulla, and spinal cord. These varied greatly in size and were largest in the medulla and anterior horn. Those in the anterior horn varied in size from the space of a single cell to occupying the whole of the grey matter. They were composed of cells with round nuclei and scanty protoplasm, cells with very irregular nuclei, an occasional polymorphonuclear leucocyte, and rarely a compound granular corpuscle.

In a few instances the polymorphonuclear cells predominated.

These clumps were not related to the perivascular changes, as they occurred independently in various sections.

It is probable that these clumps were partly formed by microglia and glia cells as well as lymphocytes.

The clumps in the medulla were often of large size extending into both grey and white matter.

The changes in the nerve cells were largely limited to the motor cells of the anterior horn of the spinal cord and to the bulbar nuclei.*

The changes may be described as follows: Nissl bodies diffusely staining; Nissl substance clumped in the periphery of the cell; complete disappearance of the Nissl bodies and shrinking of the cytoplasm of the cells.

Neuronophagia was not marked. An occasional cell could be seen surrounded by round cells, but it was only rarely that the nerve cell was replaced by the phagocytes.

The areas where cell destruction was most marked, often showed no traces of nerve cells, the whole of the grey matter being filled with cells with irregular nuclei.

Careful search revealed shrunken cells with unstained cytoplasm. Fragments of cell processes could be rarely observed. Normal cells were often present on the edges of these areas.

The changes in the nerve cells in the medulla and pons were limited to the slighter changes described, very little complete destruction being observed in the cases examined.

The destructive changes were most marked in the motor cells of the spinal cord.

Perivascular cuffing was a prominent feature of all cases. Irregular clumps of cells were diffusely scattered through the whole nervous system.

A complete report is in course of preparation.

* Gallocyanin was used to stain the nerve cells for this study, as we believed it gave more even staining than methylene blue, thionin or cresyl violet.

Clinical Features of Poliomyelitis in Los Angeles^{*}

A. G. BOWER, M.D., R.W. MEALS, M.D., MARY BIGLER, M.D.,
JOHN EWING, M.D., AND VERNON HAUSER, M.D.

Senior Attending Physician; Junior Attending Physicians; and 3 Resident Physicians, Contagious Disease Department, Los Angeles General Hospital, Los Angeles, Calif.

THE poliomyelitis seen here in 1934 was quite variable in its manifestations and difficult to describe, for there was no uniform clinical picture. The high adult morbidity was itself a variation. The symptoms were, for the most part, milder than usual, and the sequelae were less crippling. An initial toxemia was present in most cases, but this was not often severe, and the early neurological, or localizing findings, which ordinarily help to differentiate pre-paralytic poliomyelitis from the systemic phase of other acute infections, were absent in many cases. The severe frontal headache, or painful oculomotion, that is usually complained of, was not always present. Sore throat, often without local findings, was a frequent complaint. Diarrhea, often with the severe abdominal cramps and vomiting of acute gastroenteritis, was quite common. When seen without systemic or respiratory symptoms, and when developing lumbar cord findings, this was suggestive of an intestinal portal of entry.

Mental dullness at times seemed out of proportion to the degree of toxemia, a cerebral involvement common in some gastrointestinal diseases. Pain in the

cervical or lumbar areas was often present, but the usual spinal rigidity was noticeably absent in many cases. In spite of this flaccidity, however, spinal flexion, with stretch of the dura about the nerve roots, caused cervical or lumbar pain in most cases, an early finding which we called the "spine sign." Headache, or pain in the back or abdomen, induced or accentuated by slight trauma, was noticeable, even in those cases showing no increase in intrathecal pressure. The degree and duration of muscle pain, tenderness and severe cramping, were out of proportion to the motor phenomena. The treachery of the disease was more marked than usual, some cases suddenly developing nervous system findings without premonitory symptoms, and others relapsing severely after apparent recovery from mild attacks. Even more striking was the rapid, and apparently complete, recovery of some cases which appeared early to be doomed to extensive residual paralyses. The persistence of reflexes, even in the presence of marked muscle weakness, was most pronounced. Some cases showed no weakness on test, but complained of marked fatiguability.

The sensory phenomena were interesting. Hyperesthesia and accentuation of acute pain and thermal sense were sometimes limited to the extremity

^{*} Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

opposite that of the motor and proprioceptive phenomena, an indication of a unilateral myelitis. Localized profuse sweating occurred over these same areas. Temporary surface anesthesia over areas corresponding to the nerve distribution from the individual cord segments, was occasionally seen.

The degree of abdominal pain, distention, and vomiting sometimes suggested primary intra-abdominal pathology, but the absence of rigidity, and the association of urinary retention and lumbar backache, seemed to incriminate both the sympathetic and central nervous systems. Also, the sudden relief after spinal puncture, even in cases showing no increased intra-theal pressure, indicated a paralytic ileus, an uncommon phenomenon in our previous experience.

An unusual number of cases showed no increase in spinal fluid pressure, but were relieved of headache or abdominal symptoms by spinal puncture. Our explanation was the probable relief of cellular edema about the posterior horn cells, or nerve roots, occasioned by shifting of balanced osmotic pressures between the spinal fluid and the perineural circulation or lymph. The shift being toward the spinal canal would tend to reduce capillary tension, and hence edema, even though the osmotic balance between the two systems had been established at a low level.

The tendency to relapse was a constant threat, the recurrence of systemic symptoms suggesting the possibility of reinfection or activation of some focus within the body. Remote sequelae of a psychasthenic or neurasthenic nature were more common than previously noted. Insomnia and nightmare were complained of. Irritability and emotional instability were noted, and some complained of mental fatigability with poor power of concentration, all of which might be indicative of mild cerebral involvement. Neuro-circulatory

asthenia was common, the sudden weakness, vertigo, palpitation and breathlessness probably being due to sudden lowering of vascular tension incident to sympathetic dysfunction. Continued localized sweating was also of probable sympathetic origin, although the common herpes was more likely of posterior horn cell origin.

Space does not permit of a discussion of the problem of differential diagnosis. Unbelievable as it seems, we have seen 55 different conditions sent in as poliomyelitis, which proved to be something else, some of them far removed from central nervous system diseases.

Clinical observations of treatment were interesting. Prophylactic convalescent serum apparently failed to afford any marked degree of passive immunity for, of 207 of the hospital personnel thus injected, 48, or 23 per cent contracted the disease within 3 weeks. This incidence is far above the average for the population at large. These patients were, on the average, far the sickest of any group, and remained longest in the hospital. Overwork and excess fatigability are probably undoubted factors.

Convalescent serum as a therapeutic agent has proved of value, in our experience. We agree that little is to be expected of it after the central nervous system has been invaded beyond the stage of initial inflammation, but we feel that it has virtue if used in the pre-paralytic stage, and that present standards of diagnosis permit of this early recognition of the disease. The rapid abatement of symptoms following its use was usually quite striking, and this was further emphasized in those cases which relapsed 2 and 3 times and were immediately relieved on each occasion by additional serum. Intra-theal medication was not indicated in this epidemic as often as in previous ones, but we still feel that in spite of the failure of ex-

perimenters to demonstrate virus in the spinal fluid, this method of administration has proved valuable in the past, particularly the injection into the cistern in close proximity to the usual portal of entry of virus into the central nervous system. The apparent benefit may be mechanical or hydrostatic, but such cannot be claimed for the more common intra-muscular therapy. Virus has never been demonstrated in the blood, but the fact that immune bodies are present in its serum denotes a relationship, and the rapid dissemination of blood to all tissues of the body, recommends intravenous medication early to bridge the first 18 to 20 hours required for absorption from the muscles.

Immuno-transfusion has been recommended as the one most advantageous therapeutic measure. The arguments in favor of serum apply to the use of blood containing it, and in addition there is the advantage of stimulation afforded the reticulo-endothelial system. The outstanding results obtained with this form of therapy in other virus diseases is well known, but were not duplicated in this experience. The many cases of infection among doctors and nurses threatened us with a shortage of trained personnel, and in an effort to forestall such an emergency and give these patients every advantage, a blanket-order was given to immuno-transfuse all physicians and nurses in addition to giving them intra-muscular serum. This was a fortunate coincidence, for many were mildly ill, and the limited number of suitable immunedonors were consequently utilized for all patients of this group. This facilitated comparison with a parallel group treated with intra-muscular serum, but with intravenous dextrose (10 per cent in normal saline) instead of transfusion with blood. Sixty cases were transfused. Fifty-five of them were unquestionably improved within 24 hours. Five (8.3 per cent) were very much worse in a

similar length of time. Naturally there was no way of determining whether or not these patients would have been just as bad, or even worse, without the transfusions, but they were the sicker of the two groups and the transfused group were longer.

On the other hand, the dextrose-treated patients were not consecutive cases of average severity, but were the most toxic of the lay admissions. They were, without exception, markedly improved within 24 hours, some of them from a degree of toxicity that bordered on delirium, to a condition which they described as almost normal subjectively. The reason for the difference in the two groups is not obvious.

Dextrose is valuable in combating any toxemia, because of its part in stimulating hepatic glycogenesis and glycolysis, its indirect effect on hydrogenion concentration of the blood through ketolysis, and its questionable antivirucidal properties. It is not specific. Immuno-transfusion, on the other hand, is specific, but involves the factor of serum heterogeneity, independent of agglutinins, a factor which cannot be predetermined and one which constitutes a hazard difficult to evaluate. The phenomenon of allergy, or whatever explanation is offered for the spontaneous damage to the choroid produced experimentally in animals by intravenous injections of foreign serums, may have a counterpart in the occasional, unexplained cerebral reaction exhibited by patients during transfusions with apparently homologous bloods. This may account for the small percentage of bad results from immuno-transfusion. We feel that in cases showing involvement of the nervous system, in which no harm can be done by possible injury to already damaged natural barriers, that immuno-transfusion may be safely and advantageously used. There is a definite hazard attending its early use.

The 1934 Epidemic of Poliomyelitis in Southern California^{*}

GEORGE M. STEVENS, M.D., F.A.P.H.A.

*First Assistant Health Officer and Epidemiologist, Department of Health,
Los Angeles, Calif.*

ALWAYS considered baffling and puzzling, first known as sporadic disease and then, as the years went by, growing increasingly epidemic, poliomyelitis always has been protean in nature, and in this 1934 epidemic in Southern California, more than ever has the fact been demonstrated that disease and epidemics, like other affairs in this world, undergo constant change.

Never before in any epidemic have there been so many institutional cases; never so many familial cases; never so many doctors, nurses and other hospital attendants who have contracted the disease; never an epidemic of similar proportions with so low a death rate, with so many of the spinal type, so many with only paresis, or neuritis, so many of the straggling or recurrent variety, so many abortive, so few encephalitic; never before an epidemic where 80 per cent of the cases were hospitalized, more than half of them in the early systemic phase.

November and December, 1933, and January, 1934, we noticed that we were getting about twice the normal sporadic incidence of cases, 6 or 8 monthly instead of the usual 2 or 4.

In the last week of April, 1934, 9 cases occurred, and by the middle of May we found that we were on an up-

wave that was terrifying in its rapidity. The last week in May gave us a total of 95 cases, 51 for the city, and 44 for the county outside.

Alhambra to the northeast, Belvedere to the east, early became centers of infection and our spot map of the city presented almost a straight line from the Northeastern to the Southwestern part, with a particularly heavy grouping directly to the west of Belvedere into the very center of the city and the Bunker Hill district.

The peak of the wave was reached in the week ending June 9, with 220 cases: June 16 showed 199 cases; June 23, 204 cases; and June 30, 209 cases. There was a rapid rise from May 5 to the peak, then 3 weeks at an almost stationary high, since when there has been a gradual decline.

The total number of cases, city and county, to September 3, 1934, was 1,792, with 25 deaths; cases in city, 1,112, with 15 deaths; cases in county, 680, with 10 deaths; death rate, city, 1.16 per 100,000; county, 0.98; total city and county, 1.08; morbidity or case rate 73.3 per 100,000; mortality rate 1.39 per cent. The Children's Hospital had 1 doctor and 4 nurses contract the disease; the Ross-Loose Clinic, 6 nurses; the Pasadena Hospital, 1 doctor and 3 nurses; the Glendale Medical Group, 2 doctors and 1 nurse; the Orthopaedic Hospital, 1 nurse. The

^{*} Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

General Hospital (to August 27, 1934) had 2 staff doctors, 3 residents, 13 internes, 58 graduate nurses, 39 student nurses, and 22 others—a total of 137 who contracted the disease.

With the exception of the Elmonte Home for Juveniles, capacity 100, where there were 11 cases, juvenile institutions, orphan asylums, etc., were remarkably free. At Juvenile Hall, within a stone's throw of the General Hospital, where the daily turnover is 25 to 30 children, and 250 the average in residence, not a single case occurred.

Early in the year, the majority of cases occurred in those under 5; during the upwave the majority were in the 5-10 year group, the 10-15 year group coming next; but a greater number in the older groups were coming down during the 3 weeks that rounded out the peak of the wave, and since. There was an increasing tendency to attack the older ages as the epidemic waned.

The City of Los Angeles has an estimated population as of January 1, 1934, of 1,293,329, the surrounding county territory, a population of 1,013,775, making a total of 2,307,104, all served by the Los Angeles General Hospital. The New Acute Unit was opened December 12, 1933, just in time for this epidemic. Without this new unit, throwing open new wards, also making available plenty of wards in the old buildings, this epidemic would have overwhelmed us. The normal capacity of the Communicable Disease Building, 6 wards, is 245 beds, with 86 nurses. At the height of the epidemic there were 21 wards with 364 nurses caring

for 724 patients, 360 of whom had poliomyelitis.

All epidemic suspects were admitted through the communicable disease admitting room, examined, and assigned to wards as rapidly as possible. Definite cases of poliomyelitis were segregated; suspects and contacts were sifted and grouped. All suspects were held 10 days for observation, and known direct contacts for 14 days. All suspects and contacts released at the end of these periods were required to report back for muscle checks at a specified time, to avoid overlooking mild cases.

During the heavy month of June, the average daily number of suspects admitted was 103, of cases of poliomyelitis 22: a ratio of almost 5 to 1. Patients were parked on stretchers and in automobiles in the court, awaiting admission. Doctors, nurses, orderlies, maids, ambulance drivers, and all others worked overtime, often for 24 to 48 hours without let up. Fatigue, loss of sleep, and constant exposure to poliomyelitis in its most infectious stage was common to all. Slightly more than half of the hospital employees who contracted the disease were directly and constantly exposed; the others were indirect contacts.

A sufficient number of doctors who are thoroughly grounded by precept and practice in "Medical Aseptic Technique" as applied to communicable disease control, and nurses should be available to meet an epidemic of such proportions. Should not the American Public Health Association lay greater stress upon such teaching in the nation's medical and nursing schools?

Use of Serum and the Routine and Experimental Laboratory Findings in the 1934 Poliomyelitis Epidemic*

JOHN F. KESSEL, ANSON S. HOYT, AND ROY T. FISK
Los Angeles County Hospital and School of Medicine, University of Southern California, Los Angeles, Calif.

WITH the onset of the poliomyelitis epidemic in Los Angeles in 1934 it was decided to hospitalize all poliomyelitis patients from within the county and city in the Los Angeles County Hospital. This placed additional burdens on many services of the hospital, which in a few weeks increased the patients in the Communicable Diseases Unit from 240 to 750. Among duties assigned to the bacteriological laboratory were:

1. Preparing and testing serum for therapeutic and prophylactic purposes
2. Examination and cultivation of spinal fluids
3. Special laboratory work in isolating the virus and in cross-immunity experiments

It was necessary to establish new emergency units: (1) in the Communicable Diseases building where the spinal fluid work was done, and (2) for the animal experimental work. One hundred and fifty monkeys as well as a number of smaller animals were procured for the special laboratory work. Additional laboratory personnel was required and 18 second or third year

medical and graduate students, who were just beginning their summer vacations were selected. These students worked faithfully, and without their services the work here reported would have been impossible. One developed poliomyelitis during the 10th week of the epidemic. The hospital administration provided special needs whenever possible and deserve commendation for their coöperation in meeting the emergency.

The present report is preliminary since much of the work is still in progress. In preparing summaries of the laboratory work it has been expedient occasionally to refer to certain clinical and epidemiologic aspects of the epidemic for comparison. Of special interest in this connection is the group of employees who developed poliomyelitis, a certain percentage of whom received prophylactic serum.

I. PREPARATION AND USE OF SERUM

At the onset of the epidemic California as a state and Los Angeles as a community appeared to be especially serum conscious, since the state and local health departments advocated its extensive use both for therapeutic and prophylactic purposes. It was not possible from an administrative and clinical viewpoint, though desirable scien-

* Preliminary Report on the preparation and use of serum and the routine and experimental laboratory findings of the Los Angeles County Hospital Bacteriological Laboratory during the poliomyelitis epidemic. Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

tifically, to withhold serum from control groups of patients; consequently the value of the records concerning its therapeutic value is greatly reduced. Controls for the prophylactic use were found in the group who elected to take no serum.

Serum used in the Los Angeles County Hospital was obtained from two sources (1) convalescent pooled serum prepared by Dr. R. V. Stone of the Los Angeles County Health Department laboratories and purchased through the Orthopedic Hospital, (2) convalescent pooled serum and normal pooled serum prepared in our own laboratory. Altogether 121,000 c.c. have been administered to date.

All donors were checked for negative Wassermann and Kahn tests. Donors were bled individually (250-500 c.c.) into suction flasks. In many instances two donors were bled into one flask. Flasks were kept several hours at room temperature, then placed in the ice box

over night. Serums were decanted and centrifuged twice, pooled in flasks, 10 to 20 donors to a pool, preservatives added, left over night at room temperature, then put in 20 c.c. or 50 c.c. bottles and kept at ice box temperature until dispensed. The preservatives employed were:

- a. Merthiolate 1/10,000
- b. Formalin 0.2%, Glycerine 0.5%
- c. Phenol 0.25%

Aerobic and anaerobic cultures were made from first and last portions of serum removed from each 1,000 c.c. pooling flask at time of bottling, also from one bottle taken at random from each lot. Cultures were watched for 5 days and before serum was dispensed, bottles were observed in front of a light. Those showing any foreign particles were labelled "For intramuscular use only"; others "For intravenous use." The labels also showed date of pooling and the individual pooling flask from which the bottles were filled.

C.D.: Communicable Disease Unit.

Prophylactic Serum—This epidemic has afforded an unusual opportunity for the study of the value of prophylactic serum because of the unusually high degree of communicability. Among the Los Angeles County Hospital employees alone, 115 developed poliomyelitis. Many of these can be traced to contact infection. Table I shows that 11.9 per cent of employees working in Communicable Disease Unit, as against 1.3 per cent of employees in other parts of the hospital developed poliomyelitis; also that among the nurses working in the Communicable Diseases Unit 36 per cent living in the nurses' dormitories developed poliomyelitis. Among the physicians 10 per cent living in the hospital developed poliomyelitis.

Table II illustrates graphically as based on the date of onset the possible sources of infection of the first 5 nurses to develop poliomyelitis, and how they probably were factors in the rapid spread to others. It would appear that we are dealing with a standardized group of individuals since they were working and living under more or less uniform conditions during an epidemic in which the rate of communicability was exceptionally high.

Prophylactic serum was given to all

employees who elected to take it. Twenty c.c. of either convalescent pooled or normal pooled serum was given and it was recommended that this or larger doses be repeated every 2 weeks.

Table III summarizes the prophylactic serum administered to employees. It shows that 52.6 per cent of the 115 employees who developed poliomyelitis had received serum prophylactically while 47.4 per cent had received no serum, also that 14 per cent of those working in Communicable Diseases Unit who received serum as a prophylactic measure developed poliomyelitis, against 9.7 per cent of those who received no serum.

Table IV is an analysis of the prophylactic serum in terms of amounts given to the different groups. Several observations may be made: (1) Those receiving convalescent pooled serum showed no less degree of susceptibility than those who received the normal pooled serum. (2) The numbers developing poliomyelitis do not decrease appreciably as the amounts of serum administered increase. (3) Fourteen per cent of employees working in Communicable Diseases Unit who received prophylactic serum developed polio-

serum, but since the figures are so small it is impossible to attribute a great deal of weight to this observation.

CONCLUSIONS

1. There is no evidence to show that employees receiving prophylactic serum, all having a similar exposure, were more immune than those receiving no serum. In fact the percentage of those developing poliomyelitis is higher among those who received serum than among those who did not. Just why this should be is a question. One explanation might be that those who were most likely to apply for serum were subject to greatest exposure.

2. There is some evidence to show that those receiving prophylactic serum developed less paralysis than those receiving no serum.

Therapeutic Use of Serum—Since no controls were used, it is impossible to

state whether serum treated cases progressed more favorably than they would have without serum. Convalescent pooled and normal pooled serum were given to alternate cases so far as was possible, and Table VI is a summary of 575 cases to whom serum was given. This table at least indicates that convalescent pooled serum is no more effective than normal pooled serum. Higher percentages are shown among those who developed weakness and paralysis in the group receiving convalescent pooled serum than among the patients receiving normal pooled serum.

Serum Reactions—With the administration of human serum to so large a number of people an excellent opportunity was afforded to observe reactions. About 8 per cent of patients complained of some subjective reaction ranging from a mild to a severe type of serum sick-

ness, while about 40 per cent complained of painful reactions soon after injection.

A series of intradermal tests was designed in an attempt to determine the skin sensitivity of patients, and it was found that among the 8 per cent who complained of serum reactions, all of the cases tested who had received serum prophylactically and 60 per cent of those who had received it therapeutically, gave positive reactions, while a much smaller percentage of those who

had no serum symptoms exhibited sensitivity.

For the most part two types of preservatives were used in the serum, 1/10,000 merthiolate and formalin-glycerine. When reactions were reported from intramuscular injection, those receiving the formalin-glycerine complained of an immediate severe pain near the injection, accompanied by varying degrees of nausea, dizziness, and weakness. This usually subsided within 20 to 30 minutes, after which no

difficulty was observed. No local tenderness was reported at the point of injection. The merthiolate preserved serum gave no severe reactions at the time of injection but in certain instances soreness developed at the point of injection within 12 hours. This muscle soreness persisted as a rule for about 48 hours.

Tables VII and VIII give summaries of preliminary observations on this point.

II. OBSERVATIONS ON SPINAL FLUID EXAMINATIONS

There have been made to date 1,598 spinal fluid examinations on 1,300 patients diagnosed as poliomyelitis. The examinations were uniform since they were performed by a special group of technicians.

Table IX shows the cell counts. It will be observed that 27 per cent showed no cells, 38 per cent gave a count of 1-9, and 35 per cent of 10 or more. Five per cent of the total gave a positive globulin test even though no cells were present.

Table X gives a comparison of spinal cell counts with colloidal benzoin tests. Fifty-six per cent of those showing more than 10 cells gave a positive colloidal benzoin reaction against 32 per cent of those showing a count of less than 10.

Table XI summarizes the cell counts on the basis of date of onset. A higher percentage of positive counts was ob-

Globulin but no cells	85	5

tained during the first 8 days of onset than later. There was very little difference between the percentage of counts during the first 4 days and the second 4 days.

Table XII correlates spinal cell counts with severity of symptoms. This table may be compared with that of Laidlaw (1932).¹

While the percentage of those recovered without weakness fails to show any special correlation with high or low cell counts it does show that those cases which at present give indication of a permanent paralysis, and also the deaths, in most cases are among the higher cell count groups.

III. EXPERIMENTAL WORK

The special laboratory work was organized with the following program in mind. (1) Recovery of virus from the present epidemic. (2) Comparison of the virus with other strains. (3) Neu-

tralization tests with serum prepared for use in the present epidemic.

Recovery of the virus was attempted from three main sources:

1. *Brain and spinal cord of necropsy cases*—Material from the brain or spinal cord of 11 cases has been injected intracerebrally into monkeys. Monkeys from 7 of these cases have developed temperature curves characteristic of poliomyelitis in monkeys. Monkeys from 5 of the cases only have developed characteristic paralysis and exhibited histopathology in the brain and cord characteristic of poliomyelitis. Two of these strains have been selected for special study and have now been carried through the fifth passage in monkeys.*

Monkeys which have developed characteristic temperatures but failed

to develop paralysis have resisted subsequent inoculation with the M. V. strain of virus, thus indicating that recovery from the California strain produces immunity for at least one other standard strain.

The strains of virus which we have passed through several monkeys give an incubation period with an average of 10½ days. This is longer than the incubation period of the M. V. virus at present, and also longer than during its early transmission to monkeys by Flexner and Lewis in 1909.

2. *Nasal Washings*—Nasal washings from clinically positive cases, some showing positive and others negative spinal counts were inoculated into monkeys by the intracerebral route. Of 45 attempts, all were negative with the possible exception of 2 monkeys which developed a characteristic temperature curve but failed to show paralysis.

3. *Concentrated spinal fluids from cases giving positive cell counts*—Twenty-five attempts were made to in-

* Brain and spinal cord tissue from most of these Los Angeles County Hospital autopsies was furnished to Drs. L. T. Webster, J. R. Paul, and J. D. Trask, who were working in Los Angeles Laboratory at the time. Their results and ours were similar in the recovery of the virus.

TABLE XII

1-9	109	58	1		89	72
10-49	82	23	3	1	171	64
50-99	41	10	5	8	118	69
100-199	21	5	3	1	55	75
200	16	2	1	2	29	72
				1	19	84
Total	333	122	13	13	481	

fect monkeys with spinal fluid from cases with positive spinal cell counts, all with negative results.

Attempts to inoculate young rabbits, guinea pigs, rats, and mice with human tissue from poliomyelitis cases which produced positive results in monkeys were negative.

Neutralization experiments testing the antisera used prophylactically and therapeutically in the present epidemic and also testing the serum of patients recovered from the current epidemic are in progress.

The experimental work in which monkeys have been successfully inoculated with brain and cord from cases of the 1934 epidemic in Los Angeles lends support to the clinical impression that this is an epidemic of poliomyelitis, though there are many points of difference between this outbreak and other epidemics.

Some preliminary evidence has been presented which indicates that monkeys recovered from mild attacks brought on by inoculation with the California virus are immune to subsequent inoculation with the M. V. virus. This fact indicates an antigenic relationship between the two strains.

SUMMARY

The 1934 poliomyelitis epidemic in Los Angeles has been unusual in several aspects.

1. The mortality rate has been exceptionally low.

2. The amount of residual paralysis has been less than usual.

3. The percentage of adults infected has been higher than is common.

4. An exceptionally high rate of communicability has been noted, this being especially apparent among hospital employees where in the communicable disease unit of the Los Angeles County Hospital, 11.9 per cent developed poliomyelitis.

Certain preliminary observations from the laboratory of the Los Angeles County Hospital during this epidemic are as follows:

1. Employees receiving convalescent pooled and normal pooled poliomyelitis serum as a prophylactic measure demonstrated no less degree of susceptibility than employees working under similar conditions who received no serum.

2. There is slight evidence that those receiving prophylactic serum developed less severe symptoms than those who received no serum.

3. Convalescent pooled serum was no more effective when given therapeutically than normal pooled serum. Since no untreated controls were used it is impossible to evaluate the therapeutic use of serum.

4. A small percentage of the patients reported serum reactions, ranging from a mild to a severe type of serum sickness.

5. A high percentage of those who demonstrated positive serum symptoms responded to skin sensitivity tests with human serum.

6. Spinal cell counts of poliomyelitis cases demonstrated that 27 per cent showed no white cells, 38 per cent, 1 to 9 cells, and 35 per cent 10 or more cells.

7. Fifty-six per cent of those showing more than 10 cells gave a positive colloidal benzoin reaction.

8. Attempts to inoculate monkeys with virus from 11 autopsy cases have given positive results from 5.

9. The virus appears to possess an antigenic relationship to M. V. strain since monkeys which recovered from inoculation with the Californian strain are resistant to subsequent inoculation with the M. V. strain.

Orthopedic Aspect of the Los Angeles County 1934 Poliomyelitis Epidemic*

TRUSTEN M. HART, M.D.,† AND J. VERNON LUCK, M.D.
Orthopedic Service, Los Angeles General Hospital, Los Angeles, Calif.

WITH each succeeding epidemic of poliomyelitis the orthopedic aspect of the acute stage of this disease gains wider recognition and becomes more keenly appreciated. Let us hope that the day is gone forever when the practitioner and the relatives wait until the patient is paralyzed and deformed before seeking orthopedic consultation. Early consultation has, we are thankful to say, enabled the orthopedist to direct his major efforts toward prevention of deformities rather than toward reconstruction. During this epidemic the department of contagious diseases and the orthopedic department have combined their facilities—a great advantage to all concerned, especially to the patient.

DIAGNOSIS

The diagnosis of early muscle involvement has at times been difficult. During this epidemic the type of onset has been extremely variable, especially among adults. In a good proportion of cases, the onset has been, instead of sudden, extremely insidious, taking as much as 6 or 8 weeks in some instances to reach the peak of muscle involvement. Patients often walked about for days and even weeks with vague sensory disturbances, and muscle weakness be-

fore becoming sufficiently disabled or alarmed to seek medical advice. An easily fatigued leg or arm was frequently the only reason for seeking a physician. No doubt a large number of cases were missed. Patients are questioned routinely regarding the presence of painful, tender, weak, and easily fatigued extremities. The physical examination always includes palpation of accessible muscles for the presence of tenderness. If little or no muscle tenderness is noted, the strength of each muscle or muscle group is checked. We have, in the presence of more than slight tenderness, consistently followed the policy of deferring the muscle check. It was soon observed that this was an entirely logical policy. Checking muscle strength in the presence of moderate or marked tenderness is not only inaccurate but will often result in an accentuation of the tenderness.

Scores of conditions have been incorrectly diagnosed as poliomyelitis. The superficial and deep tenderness, and the arthritic manifestations of poliomyelitis must be differentiated from such conditions as acute rheumatic fever, early meningitis, acute infectious arthritis, influenza, acute osteomyelitis, acute myositis, acute bursitis, and many others. Muscular exertion by an individual leading a sedentary life may cause muscle tenderness closely resembling that due to poliomyelitis. In checking for muscle weakness the examiner must

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

† Deceased July 14, 1934.

not be misled by weakness resulting from such conditions as an old fracture, healed deep lacerations, chronic osteomyelitis, chronic arthritis, etc.

ORTHOPEDIC TREATMENT

When a patient is considered to be in the pre-paralytic stage of poliomyelitis he is observed closely for the onset of muscle tenderness or weakness. At the first signs of either sensory disturbances or weakness in an extremity, that extremity is splinted and the patient is placed on a hard bed. If the tenderness becomes marked and generalized, as it so often has, the patient is placed on a Bradford frame. Individual arm and leg splints are applied; the arm splints are bolted to the frame. The extremities and other parts of the body are splinted in a position of physiological rest, a slight advantage being given to some of the more important and more commonly involved muscles. The foot is dorsi-flexed 80° and slightly inverted, the knee is flexed 5° to 10° ; the thigh is flexed 10° to 15° ; the extremity is abducted 15° and externally rotated 10° . A small pad or pillow is placed beneath the lumbar and lower dorsal spine; its size is varied for comfort. The arms are abducted 75° and brought 30° to 40° anterior to the frontal plane of the body. The forearm is placed in 45° of supination and flexed 75° . The wrist is extended 15° , the fingers slightly flexed, and the thumb slightly adducted. If regular splints are not available immediately after muscle tenderness or weakness is observed temporary splints are fashioned from pillows and sandbags, and when properly applied and watched are satisfactory and comfortable. In certain mild cases they are all that are ever necessary. Few casts are used during the acute and sub-acute stages, but at times they are indispensable. They are used mainly on babies, small children, and uncoöperative adults (particularly doc-

tors and nurses). Casts are bivalved when dry and the top half usually discarded. The muscles and joints are palpated regularly to determine the status of the sensory changes. When muscle tenderness has practically or entirely subsided a gentle muscle check is done. If paresis or paralysis is present the impaired muscles are, if possible, splinted in a position of complete relaxation; for examples, in deltoid paralysis the arm is abducted 90° , in anterior tibial impairment the foot is dorsi-flexed 90° and inverted.

ANOMALOUS FORMS

The children have usually had a typical form of poliomyelitis, which has, in all but a few cases, been mild. Among the adults there has been a large number of bizarre and anomalous forms. A typical case of poliomyelitis in an adult has been the exception; many cases appeared to be the polyneuritic type. It is not exaggerating to say that among these older patients almost every conceivable type of sensory disturbance has been observed, and many times in the absence of definite motor paralysis. Spontaneous excruciating pain has been one of the severest manifestations. The character of the pain has been widely variable. Sometimes it is dull and boring, at other times sharp and radiating; a paroxysmal causalgic type of pain has also been frequent. Prolonged periods of muscle spasm have often been the source of severe pain; rarely excruciating spontaneous clonic contractions have occurred in lower extremities. Any physical or emotional disturbance frequently causes immediate or delayed accentuation of the pain.

Joints have been one of the most frequent and perturbing sources of pain. In many instances the joints have become exquisitely tender, swollen, and intolerant of the slightest motion. The skin over the involved joints never becomes discolored. An increase in

synovial fluid is occasionally observed, especially in the knee joint. The joints most commonly involved are ankles, knees, shoulders, elbows, and wrists. Intermingled with the various pains are all sorts of disagreeable sensations such as fibrillary twitchings, dysesthesias and paresthesias. Deep tenderness is the commonest sensory disturbance; it is most marked and prolonged at the musculo-tendinous junctions. Hyperesthesia is the next most common sensory change; it is often so intense that the patient resents even the touch of a sheet. Areas of anesthesia have been less common. One patient at present has anesthesia involving all of both forearms, with complete paralysis of both forearms. A partial or total loss of proprioceptive sense is occasionally observed in one or more extremities. Considerable tenderness is frequently observed along the nerve trunks, especially the radial, ulnar, and sciatic. Motor impairment has been as variable and bizarre as the sensory changes. There is no relation between the degree and extent of the paralysis, and the severity of the sensory disturbance. With the exception of a few cases, the motor impairment has been mild and of short duration. Many patients were found to have practically normal strength at the time when the sensory changes first subsided sufficiently to permit a muscle check.

Vasomotor and trophic changes have occurred in varying degrees in the majority of cases. The extremities become cold cyanotic, and occasionally edematous; sometimes they are moist, sometimes dry. In the more severe cases the skin desquamates and is left thin, glossy, and often red. Hypertrichosis occurs in nearly every case. The nails usually become brittle and grow faster, except in the severe cases where they temporarily cease growing. A few adults, chiefly nurses, who had their onset more than 3

months ago still have nerve trunk tenderness and generalized sensory disturbances; also painful and exquisitely tender joints that resist attempts to obtain motion in them. These cases with a clinical picture of cord changes combined with various degrees of peripheral neuritis are suggestive of infectious neuronitis.

EXACERBATIONS

One of the most interesting characteristics of many adults, especially women, is the occasional recurrence or exacerbation of certain signs and symptoms. Several conditions appear to precipitate these "flare-ups": Anger, fear, hilarity, prolonged severe pain, extreme fatigue, and sudden atmospheric changes. The outstanding symptoms are an increase in superficial and deep tenderness, severe frontal headache, vertigo, diplopia, and, most perplexing of all, vomiting which is frequently prolonged and projectile. These symptoms are almost always associated with a moderate or marked increase in intracranial pressure. A spinal tap has frequently given instantaneous and lasting relief. The duration of symptoms during these periods has varied from 1 day to more than a month. The majority of women patients have at least one such "flare-up." Some have had one after another. The consensus of opinion is that these attacks do not represent an exacerbation of the disease itself, but are more probably due to a vasomotor disturbance or instability.

ORTHOPEDIC TREATMENT (CONT.)

With children pool therapy is usually instituted soon after the quarantine period has passed, provided their general condition is satisfactory. If there is no sign of skin or muscle tenderness a carefully graduated program of muscle training is instituted soon. The utmost care is constantly employed to keep within the boundary of beginning

fatigue. While there is any evidence of superficial and deep tenderness the muscle training is deferred, but the patient is placed in the salt bath or pool and instructed to execute whatever movements he can without pain. Under this type of therapy the tenderness rapidly regresses and disappears in most cases. Pool therapy is a valuable adjunct in the treatment of poliomyelitis. Water, in a most pleasant way relieves the weak or paralyzed muscle of the antagonistic force of gravity. Patients, old and young, enjoy the water, and by it are kept in a healthy mental state, which is no small issue in the treatment of poliomyelitis. Regular short periods of gentle massage preceded and accompanied by infra-red heat, are instituted when tenderness has practically or entirely subsided, and are persisted in as long as there is any evidence of improvement.

New problems have been encountered in the treatment of adult cases. The exquisite superficial and deep tenderness together with the excruciatingly painful joint involvement have in some instances resisted for week upon end every treatment used. The scope of the treatment in these cases has been considerably limited. Because of the intense pain and tenderness and the likelihood of an exacerbation, pool therapy has had to be deferred for many weeks. As soon as they are tolerated warm salt baths are given. Most patients obtain more or less relief, although a few have been made worse. The utmost care should be exercised to avoid fatigue. Besides the baths diathermy or ultra-therm has frequently been used; it is administered over the spine and some of the more painful joints. Many patients experienced definite relief and relaxation from these treatments. In some of the severe cases of long duration joint stiffness has become a perplexing problem. In these, local infra-red heat is applied and when tolerated a program of

carefully graduated and limited passive motion is instituted.

An earnest effort is made to build up and maintain a healthy, happy mental state in every patient. This is not easy because one of the most constant symptoms of the adult form of the disease has been extreme irritability and periods of melancholia. Minds are kept occupied; most patients have radios; games are played by the less sick; and books and magazines are supplied. Thanks to Frances Marion and the late Marie Dressler, motion pictures have been made possible. Once a week a first-run "talkie" is shown for the adults, and a "Juvenile" for the children; these shows are heartily enjoyed.

STATUS OF PARALYSIS

There appears to be no relation between the severity of the onset and the subsequent muscle impairment. Most of the quarantined cases presented evidence at some time during their illness of muscle tenderness and weakness. In the majority of cases the involvement was slight and of short duration. Many patients after having had severe sensory disturbances revealed little or no muscle weakness; certain others had extensive muscle weakness, but of only 4 weeks' or less duration. A small number now after 4 months still have extensive sensory changes and muscle damage. At a later date a chronaxia study and a detailed account of residual muscle impairment will be reported. Among the older patients the upper extremities have been involved nearly as often as the lower. In the lower extremities associated muscles have been more often involved together than antagonists. Upper extremities have been more impaired distally than proximally. Children have seldom had upper extremity paralysis. Of the several hundred General Hospital patients there remain at present only 144 who have muscle involvement of any consequence. Of this

number 24 are males and 120 are females. Thirty-one of the total cases are severe and 113 are mild. The mild cases are expected to recover completely within a few weeks. Of the 31 severe cases there are 17 women, 8 girls, 2 men, and 4 boys. Nine of this group still have more or less generalized sensory disturbances; 22 have no sensory changes but have various degrees of muscle impairment—of these, 12 are adults and 10 are children. In the

adult group it is interesting to note that 6 have their muscle impairment in the left arm and left leg. In 8 of the 10 children the paresis and paralysis is confined to the lower extremities and trunks. Of the 31 severe cases it is not too much to expect that within a year nearly half will have practically normal muscle function. We are thankful to be able to look forward to a residual paralysis rate that will be, in the end, probably less than 2 per cent.

Henry Street Nurses and Tuberculosis Prevention

D^{R.} WILLIAM H. PARK, director of the research laboratories of the City Health Department, F.A.P.H.A., called on the Henry Street Visiting Nurse Service to help carry on the test of vaccination as a preventive for tuberculosis.

In a letter to Miss Marguerite Wales, General Director, he said:

We have already made very encouraging progress toward showing that vaccination can prevent tuberculosis in many cases. We have

not the means, however, to follow beyond the age of 5 years cases which were vaccinated in infancy. Until such provision is made, we will not be able to tell how long the vaccine is effective, whether only for a few years or up to adult life. This information is of great importance.

I know very well the great problem which you face in raising money to carry on your regular work, but I hope in addition that you will be able to obtain the means to follow up these cases. If you do, it will be a very great contribution to the fight to eradicate tuberculosis.

Poliomyelitis in San Francisco^{*}

E. B. SHAW, M.D., AND H. E. THELANDER, M.D.

*Communicable Disease Department, Children's Hospital, San Francisco; and
Department of Pediatrics, University of California Medical School,
Los Angeles, Calif.*

IT is not the purpose of this report to summarize completely the epidemic in Northern California. An authoritative summary of the 100 cases occurring in San Francisco has already been prepared by Geiger, Becker, and Gray. This discussion is based on the daily observation of 51 cases admitted to Children's Hospital, San Francisco, during the first 7½ months of 1934. Although the point of view is entirely clinical, this series should present a fairly valid cross-section of the epidemic, about half as many cases being included in it as were reported in San Francisco.

Incidence—During the first 6 months of the year our incidence reflected the increase throughout the state, 1 case being admitted in December, 1933, 1 in January, 1 in February, 2 in March, 1 in April, and 5 in May. A peak of 32 cases was reached in June, and there was a decline to 7 in July and 1 in August. There has been no warning so far of a rise to a secondary peak.

Age—The age distribution of these cases is not conventional. Thirty were below, and 21 above 15 years of age; the oldest was 55. The occurrence of a high incidence in the older age groups, a characteristically rural ratio, is hardly consistent with a possible theory that our relatively low incidence in a polio

year is accounted for by a high degree of immunity among the general population, nor does the fact that a few of our cases were non-local in origin fully account for this ratio.

Sex—In the age group below 15 there is the usual predominance of males in the proportion of 16 to 14, but above this age there were 7 males and 14 females, all 10 of those above 25 being females. Men are freely admitted to the communicable disease department even though only women and children are admitted to the general hospital.

Contacts—Most nurses and members of the house staff received "normal" adult serum for its possible prophylactic value, a dose of 20 c.c. or more being administered every 2 weeks during the epidemic. A rigid technic, including masking, was employed and, contrary to some experience elsewhere, no cases developed among attendants. In the general population adult serum was similarly employed to some extent and we had no cases in which this had been previously administered.

Three of the 51 cases followed known contact with the disease and 1 of these justifies especial comment. A 6 year old girl was admitted to the hospital June 13, 1934, on the 5th day of illness, promptly succumbing to bulbar poliomyelitis. Her 4 year old sister, in intimate contact until her admission, was under observation at this time for 2 days, and was given 15 c.c. of con-

^{*} Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

valescent serum from a serum pool of the Hooper Foundation. This contact developed no symptoms until 17 days after her last exposure and was then admitted with fever and signs of an upper respiratory infection. For 24 hours she apparently improved, her temperature dropped, then she became tremulous, her temperature steadily rose, and 48 hours after admission poliomyelitis was diagnosed. Lumbar puncture revealed 83 cells. Dysphagia and altered speech were evident in a few hours. She steadily and fairly promptly recovered after the administration of 2 successive daily doses of 50 and 25 c.c. of immune sheep serum. This failure of protection will be discussed later.

On the day this patient was admitted a puppy, secured after the death of the first case, became ill, developed strabismus and paralysis of the hind legs, was killed and incinerated before the parents thought of mentioning the matter.

Diagnosis—The symptomatology was entirely conventional, headache, fever, malaise, extreme fatigability, muscle pain, being common complaints. Neck stiffness was the most important physical finding in the pre-paralytic stage with tremulousness next in importance.

The spinal fluid very rarely showed any increased pressure. There was nearly always an increase in cells although 10 of the cases showed cell counts of respectively 1, 1, 3, 5, 8, 9, 11, 15, 17, and 24. In 1 of these puncture was performed only after paralysis was well established; 1 was in a severe bulbar case; 1 had a cell count of only 1 at the onset of spinal and bulbar paralysis; 1, showing 24 cells, had unmistakable symptoms following contact with a brother, ran a rather severe course and recovered entirely. In 5 cases the diagnosis was substantiated only by characteristic pre-paralytic symptomatology.

Suspects—Along with those diagnosed poliomyelitis 55 suspects were admitted

for study, in most of whom pathology not due to poliomyelitis virus was readily demonstrable. The symptoms which occasioned admission were most commonly due to respiratory infection. There were 22 patients in which tonsillitis, otitis, adenitis, bronchitis, pneumonia or influenza-like upper respiratory infection accounted for conflicting symptoms. There were 2 cases of measles and 3 of exanthem subitum. Among the suspects was 1 case of typhoid, 1 of erythema nodosum, and 1 presenting the clinical features of mild dengue, although we were reluctant to make this diagnosis in the absence of proof of a possible vector. Five patients, 3 of whom were contacts, revealed no sign of any disease. Three patients had symptoms dependent on trauma, 1 entered during an epileptic seizure, 1 during an episode of migraine, and 1 during a reaction to tetanus antitoxin.

The most interesting diagnostic problem was afforded by other types of central nervous system infection. There has been during the last several months an unusual incidence of mumps meningo-encephalitis, the authors having seen 8 cases. Four of these were among the cases admitted for observation in this series, the diagnosis being indicated by the accompanying parotitis, the lymphocytic fluid, and the course. One case of poliomyelitis developed mumps without neurological complications early in his convalescence from the former disease. One case admitted as poliomyelitis was diagnosed epidemic encephalitis, the diagnosis being borne out by the protracted course and typical findings. Three cases in the series had headache and indefinite meningeal signs along with mild dysentery.

If it is true that poliomyelitis epidemics are accompanied by innumerable sub-clinical cases of the disease, it is surprising that at a time when popular apprehension and medical alertness

were attuned to investigate the slightest symptoms, in only 6 of the 55 admissions for observation were we unable, in the presence of some evidence of illness, completely to rule out sub-clinical poliomyelitis or make a positive alternative diagnosis. If the present epidemic was accompanied by many sub-clinical cases most of these must have been entirely asymptomatic.

It has been a common observation that epidemics of poliomyelitis occur during periods when other epidemic diseases are not present. In contrast to this, the present epidemic occurred during the wane of measles incidence and when there was coincidentally a great deal of respiratory infection and other forms of acute illness. The differential diagnosis of influenza-like upper respiratory infections with headache and generalized pain, measles, and other of the acute infections mentioned, from poliomyelitis was a difficult problem particularly because of the occurrence of mild cases of poliomyelitis and of a very few with normal or nearly normal spinal fluids.

Treatment—In the treatment of these cases we have proceeded on the belief that convalescent serum, the serum of immunized animals, or the transfusion of large amounts of normal (and potentially immune) blood offers a legitimate hope of specific therapeutic effect. Our eagerness to employ these measures definitely encourages the beneficent by-effect of early observation with the consequent employment of prolonged rest and the early use of orthopedic measures.

Our present and past cases are insufficient to permit statistical conclusions regarding the efficacy of treatment, and we have always avoided drawing arithmetical comparisons as an index to therapeutic effect. The propriety of basing an opinion upon the purely numerical end results in treated and untreated cases may be questioned for

several reasons. It is, of course, obviously incorrect to treat all early cases and use those admitted late as "untreated controls." Conversely, if alternate cases are selected for treatment, the results in treated and untreated cases can be compared only if similar conditions prevail throughout the series.

It is difficult to conduct a clinical experiment along the lines pursued in the laboratory even if one were temperamentally able to resist the tendency consciously or unconsciously to select one's cases. In the laboratory, controls are employed for each variable in an experiment, but it is impossible to provide adequate controls for the innumerable variables which exist in this clinical experiment. These experimental variables affect the patient, the disease, and the therapeutic serum.

Patients manifest different responses to the disease and at the same time to the effect of therapy because of age, size, individual variations in immunity, and because of alterations in the immunity of the individual occasioned by fatigue, physical changes, the influence of other infections, etc.

Variations in the infection occur with respect to individual epidemics, season, location, and the changes in virulence which accompany the rise and fall of an epidemic. The effect of variations in the dosage of the infecting virus, dependent on the duration and intimacy of exposure, is commonly not considered although the influence of this factor on the intensity of disease may be clearly seen in other childhood infections.

Convalescent serum obviously falls far short of the antibody content of therapeutic serums employed in other diseases. It is difficult to evaluate quantitatively the antibody content of any antiviral serum, but there must be a tremendous variation among those used in poliomyelitis. All types of serum are employed in therapy, moreover, in various amounts. A proper

quantitative relationship between the age, size, and response of the patient to the severity, localization and stage of the infection, and the amount and "titer" of a therapeutic serum which must be employed to constitute effective therapy is yet to be established. This has been done in other infections in which specific therapy is successfully employed; without such a scheme of treatment it might be difficult to evaluate statistically the effect even of antitoxin in diphtheria.

The real problem, as yet unsolved, is whether or not any patient with poliomyelitis can be benefitted at any stage by any amount of serum. We have tried to meet this problem by treating cases at the earliest possible moment with large doses of serum repeated at very frequent intervals, and in the case of a convalescent serum varying the source. The view that the serum has effective properties is somewhat discouraged by the incident quoted earlier in which the disease followed exposure despite the prophylactic administration of 15 c.c. of convalescent serum. Such occurrences, however, are not uncommonly encountered in the prophylaxis of measles with convalescent serum and although they are equally hard to explain they are insufficient to discredit the fact that measles convalescent serum usually protects against this disease. Measles prophylaxis presents other points of similarity which might be mentioned inasmuch as it is here also necessary to regard quantitative relationships between age, size, degree of exposure, elapsed time after exposure, and dose of serum. The possibility that in poliomyelitis, as in measles, modification of the disease by serum rather than complete ablation of all symptoms may be brought about, must be borne in mind, and the observations over the last 10 years encourage us in this belief.

It comes—The course of the cases in the present epidemic favors the opinion

that convalescent serum is a beneficial factor although obviously it was not the sole factor influencing a favorable or unfavorable outcome. In some cases prompt improvement followed serum therapy and the whole infectious picture presented by the patient was markedly altered. This effect was seen particularly in patients with high spinal fluid cell counts and typical symptomatology in which over a period of 2 to 5 days prior to treatment there was little change in either direction. In a number of these the improvement following serum was so prompt both subjectively and objectively that the influence of therapy was almost unquestionable. In other cases there was a slower subsidence of symptoms but the end result seemed materially better than could reasonably have been predicted, granting the difficulty of such predictions. Only rarely were end results unfavorable and in these it was impossible to be sure that adequate antibodies were applied sufficiently early.

In this series there were 17 cases which were treated preparalytically in which both clinical and laboratory evidence clearly substantiate the diagnosis. In 15 of these, following intensive serum treatment there developed only very slight and transient paralytic phenomena which had completely cleared by the end of the 3 weeks of isolation. These favorable cases include a few regarding which we were optimistic from the outset, a number in which the outcome was characteristically unpredictable, and several in which the symptoms were so severe as to justify a very unfavorable prognosis. In 2 the results were unfavorable, 1 represents a failure of what we regarded as adequate therapy, the other was treated, we feel, inadequately for 3 days before entering the hospital badly paralyzed and still in the febrile stage.

In all of the cases which entered the hospital after paralysis was evident but

in which active symptoms of infection still persisted, specific therapy was applied. In these cases it is impossible to arrive at more than an impression regarding beneficial effects, but this impression is that a certain amount of modification of the disease was brought about by specific therapy. Such a therapeutic result may be compared

with that effected by the transfusion of large amounts of immune blood during the febrile course of measles. An especially favorable effect was observed in bulbar cases in which paralytic symptoms commonly appear almost coincidental with the initial rise in temperature and in which a grave prognosis is usually justified.

Borough of Willesden, England

THE 1933 annual health report of the Borough of Willesden, England, reveals many interesting health activities. The estimated population for mid-summer 1933 was 190,875, the area 4,384 acres, giving an average of 43.3 persons per acre. The general death rate was 9.88 against a birth rate of 13.99.

The infant mortality of 46.05 per 1,000 births was the lowest rate ever recorded for Willesden. About 36 per cent of expectant mothers attended prenatal clinics conducted by the health department, while 46 per cent of the births took place in hospitals. Midwives are directly under the supervision of the health department, being trained in the Maternity Hospital. There were 13 cases of puerperal fever, 4.7 cases per 1,000 total births; 4 of the cases were fatal. Each case of puerperal fever and each death occurring in childbirth are investigated by a consulting obstetrician. The Maternity and Municipal hospitals are under health department supervision.

There were 392 cases of diphtheria,

11 deaths; 1 of smallpox, no deaths; 13 of typhoid fever, 1 death. Four small outbreaks of food poisoning were investigated; the largest of these, affecting 23 persons and causing one death, was attributed to staphylococcus aureus by the Pathological Laboratory of the Ministry of Health.

To combat the increasing death rate from cancer, bi-monthly clinics are held at each of two centers, for the purpose of diagnosis. In addition arrangements are made with certain large London hospitals for referring patients for further diagnosis and for treatment.

Children are examined and attempts are made to correct defects in the secondary and trade schools, as well as in the elementary schools. Much dental work is done for children from infancy until they finish elementary schooling, and for expectant and nursing mothers. At four feeding centers in the city, breakfasts and dinners are provided to school children of unusually poor parents. Children who pay may also obtain hot dinners at these stations.

Western Public Health Problems*

J. L. POMEROY, M.D., F.A.P.H.A.

Los Angeles County Health Officer, Los Angeles, Calif.

TODAY in connection with our parent organization we open our Fifth Annual Meeting since the birth of the Western Public Health Association in 1930. There is no doubt whatever that the Western Public Health Association has ably served its purpose of promoting professional intercourse in the western part of the United States, and furthering the interest of the public health of the people. In spite of the fact that the association was launched during the depression, attendance at meetings has been gratifying. The western states not only have the usual problems of public health and sanitation common to the rest of the country, but also problems that, because of our climate and our nearness to the Orient, are of special significance to health officers in this section. It is gratifying to note the splendid support given our organization by the American Public Health Association, and we hope that when financial conditions are better support may be increased.

If the Western Branch is to accomplish its best results, substantial endowments and contributions of money should be secured.

I feel the organization owes a great deal to the time and effort spent by our able secretary, Dr. W. P. Shepard, without whose services the organization

would be seriously handicapped. It is not too much to hope that in the future our organization may look forward to a full-time secretary with at least a modest budget.

There are several urgent problems before western public health officers, a few of which we may mention here. Psittacosis presents a unique problem in public health control. The known facts definitely connect the presence of infected psittacine birds with the spread of this disease to human beings, nevertheless, control measures have been extremely difficult and, unfortunately for California, the disease has caused outbreaks in other sections of the country. This disease illustrates the exposed character of the western states, because there is evidence to show that it was introduced into California from Brazil. Nothing short of extirpation of all infected birds in California will suffice for its eradication. According to U. S. Public Health Officer V. M. Hoge (*Public Health Reports*, 49:451 (Apr. 6), 1934), there is a long list of susceptible species of birds, which includes poultry. This situation in regard to psittacosis serves to emphasize the need for extension of the research resources on the Coast, both from the U. S. Public Health Service and through private support.

Plague continues to be a serious menace not only to California but to the entire coastal area. Recently, in Kern County, Calif., an area of approximately 409 square miles, was found to be heavily infected with plague in ground

* Address of the Retiring President, Western Branch, American Public Health Association, delivered at the Sixty-third Annual Meeting of the American Public Health Association and Fifth Annual Meeting of the Western Branch, in Pasadena, Calif., September 2, 1934.

squirrels. The total area involved, including a portion of Tulare County, is 945 square miles. One infected child was reported in this area, and more human cases would have occurred except that the district is sparsely settled. Plague has been proved, by dissection and laboratory tests, in 162 squirrels (Selvatic Plague, Its Present Status in California, K. F. Meyer, Ph.D., *California and Western Medicine*, 40:407 (June), 1934). Needless to say, the situation is receiving prompt and efficient attention in the eradication of ground squirrels. A proposed state-wide program under S.E.R.A. for an intensive ground squirrel eradication is under consideration.

Other diseases which give us marked concern in the western states are undulant fever, Rocky Mountain spotted fever, tularemia, rabies, and tuberculosis. This list is not an exhaustive one, but these are perhaps the most important.

In regard to tuberculosis, of course, our problem has been one mostly of the importation or migration of cases from other parts of the United States. Nevertheless, with our growing population we can truthfully say that we have a problem of indigenous tuberculosis as well. It is noteworthy that in the last 20 years the tuberculosis death rate in California has been reduced from 198.3 per 100,000 population, to 72.3. It is surely necessary that we greatly extend our efforts in regard to this common communicable disease in the finding of missed cases in the search for contacts, and in proper hospitalization and isolation of infective persons.

I need scarcely remind this audience of the discovery by McCoy in 1911 of tularemia in Tulare County, and the fact that this disease is quite widespread throughout this area. Coccidiodal Granuloma was also discovered in California by Rexford in 1894; and Ophüls and Ash in 1905 discovered the *oidium*

coccidiodes, the general source being located in the San Joaquin Valley.

It is interesting to note that the first reported death from rabies in California occurred in 1892 from a skunk bite. We must admit with shame that rabies is still very prevalent, and that adequate measures for its eradication have not received public support. Recently in San Diego a young girl died from this disease, and last year one death occurred in Los Angeles County.

Since the work of Dr. Charles Browning, of Highlands, on the black widow spider (*latrodectus mactans*) in 1901, additional research by Bogen and Berman of Los Angeles County has revealed this spider as a serious menace and the cause of quite a few deaths, the true origin of which had probably been overlooked.

The menace of botulism, as a result of the pioneer work of Wilbur and Ophüls, followed by Dixon, Geiger, and Karl Meyer, has been very much lessened. Nevertheless, we must constantly be on guard in supervision of canning, particularly of home methods. It is rare indeed that any case of botulism is traced to commercial canning, so effective have been protective measures. We must continue to insist to the public that *all home canned vegetables and other non-acid foods should be thoroughly boiled before use*. Any canned product which has a leaky lid or an "off odor" should be treated with suspicion and, above all, no householder should even taste any suspected products.

The early work of Kellogg and Kilyoun with plague in 1894 may be recalled to your minds. The struggles during that early period with the politicians should give us some sense of gratification when we consider the prompt response of states and municipalities to our requests for aid in the presence of this menace today. The influence of Rupert Blue in those early

days has been felt throughout the state to the present time. We must admit, however, that there is much progress yet to be made in some of our large cities which are derelict in not providing proper rat-proofing of buildings and other measures.

Diphtheria antitoxin was first used in Los Angeles City in 1895. Los Angeles City was also one of the first, if not the first, to establish a municipal nursing system, which it did in 1898.

Smallpox is still a menace in our western states, especially in California, because of the peculiar resistance we meet from the cultists. This situation is worthy of some analysis. It appears historically that cultism and irregular practitioners of medicine have been a problem in California and perhaps in all of the western states since the earliest days. Although California was the third state of the Union to establish a State Board of Health, having done so on March 8, 1870, nevertheless, the struggle against quackery began early and still continues, and is mostly unsuccessful. The first Medical Practice Act in the State of California was established in 1876, and included not only the regular M.D.'s but homeopathy and eclecticism. The first secretary of the State Board of Health, Thomas M. Logan, made many notable advances, and was a man of great energy and ability. He was also the first resident of California to be president of the American Medical Association.

It is interesting to note that in 1885 the total number of certificates issued by the Board of Examiners of the California State Medical Society was 1,698; the number issued by the homeopathic boards, 217; by the eclectic board, 294; total, 2,209; the number of persons practising medicine without a license was 425. The proportion of population to each licentiate was 1 to 838. In 1925 after the passage of the chiropractic initiative in 1923, an estimate made

by Musgrave (*California & Western Medicine*, 23:598 (May), 1925) calculated that there was one doctor of some sort operating to each 100 population—about 31,000 altogether. Of these, only 8,000 held physicians' and surgeons' licenses. The author admits that the licensing system has not protected the public from cults and quackery.

A recent survey made in Los Angeles County by myself gives the following figures: total practitioners of all kinds, 7,636; regular M.D.'s, 3,918; osteopaths 927; chiropractors 1,440; optometrists 550; Christian Science practitioners 1,200; naturopaths and midwives 101. It is significant that the 1,440 chiropractors have come into being since 1921. Throughout the United States it is estimated that \$125,000,000—a sum equal to the entire amount spent on public health—goes to the irregular group of persons practising medicine. I have estimated that if the amount spent for patent medicines and quackery could be entirely eliminated, the income of each regular medical man in Los Angeles County would be increased annually between \$3,000 and \$5,000. A recent book by a newspaper writer, Morro Mayo, states as follows: (Los Angeles, by Morro Mayo, Knapf & Co., 1933, p. 269):

In addition to its preëminence in the fields of material progress, morality, and patriotism, it is universally recognized that Los Angeles leads the world in the advancement and practice of all the healing sciences, except perhaps medicine and surgery. Eastern medical science having failed either to rejuvenate the members of that multitude of the aged which each year escapes from harsh winter, or to perform magic for the accompanying army of the sick, many of these people gravitate naturally to the practitioners of divine healing, fortune-telling, and miracle-making, all of which are legalized professions in Los Angeles. The City of the Angels has more osteopaths than any city in the world, and in proportion to its own estimate of population three times as many chiropractors as any other municipality on earth.

The city is internationally famous for its metaphysical versatility, and each year erstwhile Christians in alarming numbers desert the orthodox evangelical churches for temples more bizarre. It is largely, perhaps, a climatic phenomenon. After the frozen folk of Vermont and Wisconsin have been exposed to the melting atmosphere of Southern California for ninety days, a subtle change comes over them. Thereafter they demand something more exotic, if not more erotic, than the frigid stuff to which they have been accustomed. This accounts for all the theological love-cults and spiritual schools of sex aberration. Briefly, it may be set down that any geomancer, soothsayer, holy jumper, herb-doctor, whirling dervish, snake-charmer, medicaster, table turner, or Evil Eye—practising any form of black magic, demonology, joint-jerking, witchcraft, thaumaturgy, spirit-rapping, back-rubbing, physical torture, or dietetical novelty—any such will find assured success and prosperity in Los Angeles despite fierce competition. All kinds of quacks, therefore, have poured into Los Angeles and Southern California for the last twenty years.

The greatest of these, one of the most remarkable women on earth, was, and is, the Reverend Aimée Semple McPherson.

California particularly has been more or less held up to the United States as the home of quackery. A brief examination shows, however, that California has been much sinned against. Osteopathy is an importation from Kirksville, Mo., this school having been originated there in 1896 by Andrew Still. Andrew Still himself places the date as June 22, 1874. The Pacific College of Osteopathy was started in Los Angeles in 1896. For this contribution we have Missouri to thank. The next group, which is now the largest—chiropractic—is an importation from Davenport, Ia. There, in 1894, B. J. Palmer brought to the light of the world the discovery that the nerves which emerge from the spinal column become pinched through twists and defects of various kinds, and therefore cause all kinds of diseases. We have Concord, N. H., to thank for the development of Christian Science. It is interesting to note that as early as 1884 the California Metaphysical Institute

was started by emissaries of Mary Baker Eddy. New York contributes the Theosophical Society, and Katherine Tingley founded the Point Loma Society in San Diego in 1875. Kansas City, Mo., contributes naturopathy, nudism, Unity, and chirothesia. Our most shining example locally of faith healing, hypnotism, mesmerism, and publicity in general, comes from Ontario, Canada—our unparalleled Aimée Semple McPherson. To San Francisco we look for Brother Abrams, now departed, with his box, oscilloclast, and other doo-dads.

The exact origin of the anti-vivisectionists I have been unable to locate. It is noted, however, as early as 1896 an organization appeared in Massachusetts. We therefore might voice the suspicion that this state contributed the pest of anti-vivisection to the West. It may be truly said that Bernarr MacFadden has created a school of physical cultists who, by reason of their opposition to our organized public health procedures, have multiplied our difficulties. To New York we may give credit for the development of this source of our difficulties. Therefore, while it may be true that cultism, possibly because of our climatic and other conditions, flourishes nobly on the Pacific Slope, we may justly claim they are importations, and not indigenous. In many respects we would be much better off with our Indian medicine men, who at least knew nothing about high pressure salesmanship.

During the course of the year your president submitted to a number of prominent public health authorities throughout the United States, and to officials of the American Public Health Association, a proposal of the Los Angeles County Medical Association in which definite demands were made to delimit sharply the work of the public health officer. These data were compiled, copies made and bound and made available to members of our Western Public Health Association. Much

favorable comment has been received as a result of this survey of opinion. A few copies are still available, through the author, for those who wish them.

Briefly speaking, there is no doubt that certain elements among our medical fraternity are desirous of eliminating all treatment of any kind from the program of health departments, even including the giving of advice on formulas and diets in our well-baby conferences. Health education is to be limited to the masses, and not to be given to individuals. Physical examinations are to be confined to those suspected of tuberculosis and venereal diseases, but no treatment whatever is to be given. The X-ray must be turned over to welfare departments. Health camps and preventoria are to be administered by welfare departments and not health departments. Vaccination and immunization must be done, except during epidemics, by private physicians, and fees paid therefor by the health department. Public health nurses must not call on any family of patients being cared for by private physicians except with their consent. As a result of this movement, the State of California now has a clinic bill which, except for the protest of myself and the school physicians, would have placed under a license system even the routine work of the health officer in prevention. A formal charge has been lodged against the health officer that public health work tends to encourage pauperization, and that the medical work of the health department should be entirely limited to those who are certified as indigents by the welfare department.

Time does not permit a complete analysis of these problems. The American Public Health Association at its meeting in Indianapolis adopted an official declaration of attitude on the basic health services of health departments. This declaration stated that leadership and responsibility should be

vested in full-time trained health officers appointed by professional qualifications, and reiterated that the annual appropriation for official health work should be at least \$1 per capita.

In tuberculosis control, the X-ray was an absolute essential for diagnosis and checking of progress. In the handling of venereal diseases the clinic was recognized as a necessity. In the promotion of child health, provision for prenatal care, infant welfare, preschool and school hygiene were stressed. Duplication between school health services and public health services is to be avoided. The demonstration of sound methods in child hygiene and the provision of personal services were approved, especially where these services could not otherwise be obtained. Public health education, both through mass efforts and personal and group demonstrations, was approved. Research work in all lines of public health work was stressed. It was noted that the health officer should participate in the planning and coordination of all health activities in his community. Health conferences, or preventive health center medical services, were justified as a means of creating a demand for such services, as an agency for inaugurating proper standards, and to supplement the preventive services of private practitioners. Diagnostic facilities and clinical treatment for communicable diseases, and individual instruction in personal hygiene through medical conferences and visits by public health nurses should be provided by health departments for all persons needing such services and not in a position to obtain them, under conditions which make their general utilization reasonably probable. In deciding whether a given health procedure should be conducted by the department itself or by individual medical practitioners or other agencies, the primary consideration should be the welfare of the community, and where

efficiency and economy are reasonably equal preference should be given to a program which decentralizes health procedure so as to enlist the private practitioner in carrying them out.

In the organization and make-up of the Los Angeles County Health Department there are 25 full-time medical officers, and 52 part-time medical men. Thus there are more than twice as many men employed by the health department who are also in private medical work than there are full-time men.

In regard to the program of immunization against diphtheria and smallpox, we immunized against diphtheria last year 16,929 persons with a cost of \$.41 per person. We immunized against smallpox 19,655 persons at an average cost of \$.23 per per-

son. We spent \$3,000 on a program wherein 16 nurses visited 18,000 homes and endeavored to send the children to the private physician for immunization. Only 500 immunizations resulted, which makes the cost \$6 per immunization. I therefore question whether as a matter of economics the average health officer can afford to adopt the Detroit Plan of paying \$2.50 per person for immunization which can be performed by the department for from \$.25 to \$.50 per person. Economics to a large degree will answer this question.

In closing, may I express my appreciation for the honor which has been bestowed upon me, and may I express the hope that the Western Branch of the A.P.H.A. will have a splendid and rapid growth in the future.

National Recreation Congress

BRINGING together the strands of many national and local movements for the enrichment of American life, the Twentieth National Recreation Congress, held in Washington, D. C., October 1-5, 1934, presented as complete a picture as this generation has had of the progress and problems of public recreation in the United States. There were 24 section meetings, 4 symposia, and 8 general sessions. The 900 delegates attending considered the swiftly declining birth rate, the plight of thousands of young people out of school and college and unwanted in industry, the idleness of the millions of older un-

employed, changing interests of Americans in their leisure, shrinking appropriations for recreation, and other questions.

Significant of the federal government's new aggressiveness in developing the nation's recreational resources, and particularly its lands, were the reports made by representatives of the National Park Service, National Forest Service, Office of Education, The Children's Bureau, the Agricultural Extension Service, the Federal Emergency Relief Corporation, the Subsistence Homestead Corporation, the Tennessee Valley Authority, the Biological Survey, and the National Resources Board.

Secondary Cases of Certain Communicable Diseases Among Non-Immune Family Contacts

F. L. KELLY, M.D., F.A.P.H.A., AND ELEANOR REITE

Department of Hygiene, University of California, Berkeley, Calif.

IN order to determine the relative infectivity of scarlet fever, mumps, chicken pox, whooping cough, and measles, a study was made from data for 1930, 1931, and 1932, secured in Berkeley, Calif. The number of secondary cases among susceptible family contacts was obtained and the secondary attack rate per 100 of these contacts was computed. The observations were made from epidemiological histories of 105 cases of scarlet fever, 1,716 of mumps, 1,456 of chicken pox, 1,043 of whooping cough, and 2,344 of measles, all of which had been reported to the city health department.

The following definitions are used in this study:

Primary case—The first case appearing in a family. When 2 cases appeared simultaneously or when 1 followed the other before the expiration of the minimum incubation period only the first case was listed as primary with susceptible contacts, the second being classified as primary cases with no susceptible contacts.

Susceptible contact—Any person in the family group who did not give a history of a previous attack of the disease. In this study it was impossible to separate the susceptible children and susceptible adults. For this reason the group of susceptible contacts may be fictitiously large as some of the adults

may have had a previous attack which was forgotten. However, the histories were all taken by trained public health nurses and every effort was made to obtain accurate information.

Secondary case—Any member of the family group developing the disease after the expiration of the minimum incubation period, dating from the onset of the primary case.

Secondary attack rate—The percentage of susceptible family contacts that developed the disease.

The secondary attack rates for the 5 diseases studied are shown in Table I. They bear out the generally accepted idea that scarlet fever (secondary attack rate 6.0) is relatively less communicable than the other common communicable diseases,¹ that measles (50.5) is highly communicable, and that the communicability of mumps (26.9) chicken pox (38.8), and whooping cough (40.9), falls between the 2 extremes.²

The secondary attack rate of measles is more than 8 times that of scarlet fever, in spite of the fact that approximately twice as many susceptible persons were exposed per primary case in scarlet fever as in measles, the ratios being 3.1 and 1.6 respectively.

The secondary attack rate of 50.5 for measles is somewhat lower than that found by other observers. This is

TABLE I
ATTACK RATES AMONG SUSCEPTIBLE FAMILY CONTACTS
SCARLET FEVER, MUMPS, CHICKEN POX, WHOOPING COUGH AND MEASLES

	Total number cases	Primary cases no susceptible contacts	Primary cases with susceptible contacts	Number of susceptible contacts	Number of secondary cases	Secondary attack rate
Scarlet fever	105	9	81	250	15	6.0
Mumps	1,716	433	806	1,770	477	26.9
Chicken pox	1,456	447	572	1,126	437	38.8
Whooping cough	1,043	344	402	726	297	40.9
Measles	2,344	909	800	1,258	635	50.5

probably because of the difference in the age composition of the groups studied and because only those cases developing after the minimum incubation period were used in computing our rates. Chapin³ found a secondary attack rate of 76.2 among 8,300 susceptible persons exposed to 8,043 primary cases. However, he included among his secondary cases every case in the family except the first, even those developing on the same day with the primary case. If the 1,723 cases developing during the first 7 days of illness of the primary case are excluded from Chapin's series the secondary attack rate is 65.1, not

greatly in excess of that found in this study. The rate of 53.3 found by Halliday⁴ is based on a study of 120 susceptible contacts living in tenements in Glasgow under such conditions that "from the epidemiological standpoint, each tenement building described may almost be regarded as a household in itself." Of the 120 susceptibles 64 developed measles but in this number were 13 primary cases. If the primary cases are subtracted it leaves 107 susceptibles, 51 of which developed the disease, a secondary attack rate of 47.7, slightly lower than that found by us. Butler⁵ found that of 3,039 susceptibles

TABLE II
COMPARISON OF ATTACK RATES AMONG SUSCEPTIBLES
MEASLES

	Chapin		Halliday		Butler	Kelly and Reite
	Original	Corrected	Original	Corrected		
Susceptible contacts	8,309	8,309	120	107	3,059	1,258
Secondary cases	6,333	4,580	64	51	2,023	635
Secondary attack rate	76.2	55.1	53.3	47.7	66.1	50.5

5 or more	11	3	0.27	1.45	1.45	290	54	0.28	258	122	0.47	206	108	0.52	496	255	0.51	255	0.51

exposed in the home, 2,023 developed measles, a secondary attack rate of 66.1. He does not state whether primary cases and only those developing the disease after the minimum incubation period were included among the 2,023 cases. Table II shows the above rates, both the original and those corrected, to correspond as closely as possible to the group studied by us.

In order to determine if the secondary attack rate varied significantly in families with different numbers of susceptible persons, a grouping was made according to whether 1, 2, 3, 4, and 5 or more susceptibles were exposed. The rates were computed for the different diseases by groups and are shown in Table III. While the numbers are not sufficiently large in some of these groups to warrant drawing definite conclusions, it is evident that there is no fixed relationship between the secondary attack rates and the number of susceptible family contacts.

While the secondary attack rates do not increase or decrease regularly according to the number of susceptible contacts, Table IV shows that secondary cases resulting from each primary case shows a steady increase from the 1 susceptible contact group to the 5 or

more groups for each disease except scarlet fever and chicken pox, and in the latter it is true except for the group of 5 or more contacts. The smallest increase was in scarlet fever from 0.20 secondary cases per primary case in the group with 3 susceptible contacts to 0.47 in the group with 4 susceptibles. The greatest increase was in measles from 0.51 secondary cases per primary case in the 1 contact group to 3.0 in the 5 or more.

SUMMARY

1. Measles has the highest infectivity of any of the diseases studied.
2. The secondary attack rates among susceptibles of any of the diseases studied do not vary uniformly according to the number exposed in the family.
3. The average number of secondary cases per primary case increases as the number of susceptible contacts increases, but there is great variation among the different diseases.

Silicosis*

A Study of 106 Pottery Workers

PAUL A. QUAINANCE, M.D.

Associate Medical Director, Golden State Hospital, Los Angeles, Calif.

PNEUMOCONIOSIS, a "disease due to breathing air containing silica (SiO_2) is characterized anatomically by generalized fibrotic changes and miliary nodulation in both lungs, clinically by shortness of breath, decreased chest expansion, lessened capacity for work, increased susceptibility to tuberculosis,"¹ and roentgenographically by diffuse nodular or confluent pulmonary shadows, increase in peribronchial and hilar densities and decreased excursion of the diaphragm.

INCIDENCE

Hippocrates described the breathing difficulty of metal-diggers. Agricola,² in 1557, wrote: "When the dust is very corrosive it ulcerates the lungs and produces consumption. Hence it is that in the Carpathian Mountains there are women who have married 7 husbands, all of whom this dreadful disease has brought to an early grave." Löhneiss,² in 1690, recorded that "... the dust and stone fall upon the lungs, the men have lung disease, breathe with difficulty, and at last have consumption." Ramazzini³ first described the grating sound produced by cutting the lung tissues of stone and

coal workers early in the 18th century.

Although observed in every industry where silica-laden air is encountered, pneumoconiosis was not scheduled as a compensable occupational disease until 1910 when New Zealand included it under the Workmen's Compensation Act and almost immediately rescinded the action (Sayers²). Interstitial pneumonia, or miners' phthisis, was recognized among the zinc and lead miners of Utah and Nevada in the same year. It had been known in the Transvaal in 1899. Today silicosis ranks with the dermatitides as one of the most important occupational diseases which McCord⁴ aptly has termed "Medicine's Unclaimed Province." It is estimated by Lanza and Vane⁵ that in the United States fully $\frac{1}{2}$ million workers are exposed to silica dust in the chief mining, quarrying, rock-drilling, clay products, and associated manufacturing industries. Pneumatic tools and natural stone grinding wheels have made silicosis world-wide.⁶

An acute form of the disease occurs with symptoms manifested as early as 3 years after initial exposure to mixtures of silica and soap alkalis. Such cases have been described in soap powder grinders and packers by Chapman⁷ and MacDonald,⁷ in scouring powder workers by Kilgore,⁹ in sand blasters by Foord,¹⁰ and others, and in lens grinders by Russell.¹¹ Death usually is from terminal pneumonia or tuberculosis.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 5, 1934. Read (in part) before the Industrial Medicine and Surgery Section of the California Medical Association at the sixty-second annual session, Del Monte, April 24-27, 1933.

A more gradual development of silicosis was found by Clark¹² in two-thirds of a group of carborundum and carbide workers with average occupation period of 10 years. Lawson, Jackson and Gardner¹³ found 9 of 17 iron miners with exposure of 3 to 8 years, to have died during the following 21 years. The remainder showed rapidly progressing fibrosis. Lanza¹⁴ reported the average age at death of zinc miners in Missouri as 36 years and the life expectancy of iron ore workers as 9.6 years. In 1900 Murray reported an asbestos worker who was the only living survivor of 11 men entering that industry 10 years previously. Asbestos dust enters the lungs as a silicate rather than as the oxide of silica.

Characteristically pneumoconiosis develops insidiously and symptoms are latent. Thus Britton and Head¹⁵ saw a granite worker and a knife grinder each with only 4 months exposure who first developed symptoms 23 and 14 years later respectively.

In a comprehensive review, Pancoast and Pendergrass¹⁶ found fibrosis in 74 per cent of 495 sandstone workers, and in 57 per cent of 208 rock drillers with average exposure of 21 years. Fifteen per cent of those affected had third stage silicosis. Fifteen of 20 cement plant workers exposed over 7 years had slight fibrosis. Orr¹⁶ reported second stage silicosis in a buck-and-wing dancer who for 25 years had scattered sand on the stage before each performance. Mills¹⁸ found advanced fibrosis at autopsy on a man who had worked in an asbestos mine 32 years previously for a short period only. In hard coal miners with average exposure of 11 years, Tattersall¹⁹ found silicosis developing slowly and insidiously. In Welsh coal miners after 20 years' service, Cummins²⁰ found the lungs to contain large amounts of both rock and coal dust. In his experience silicosis appeared long before tuberculosis de-

veloped and coal miners were not very susceptible to the latter. McFarland,²¹ and Russell, *et al.*,²² found silicosis to be almost universal in granite workers (Barre, Vt.) with an unusual susceptibility to tuberculosis after 20 years' exposure. Head and Rosenblum²³ found 3.7 per cent of 500 males admitted consecutively to Cook County Tuberculosis Hospital to have tuberculo-silicosis.

PATHOGENESIS AND PATHOLOGY

The crystalline and amorphous silica compounds (SiO_2) comprising rock crystal, quartz, quartzite, flint and sandstone, are the chief producers of silicosis. Lemon and Higgins²⁴ emphasize the point that more than 10 million particles of silica per cu. ft. of air and a size of less than 10 microns are essential to any appreciable silicosis hazard. As high as 92 million particles have been determined.

Many observers (Belt,²⁵ Lemon and Higgins,²⁴ Russell,²² Mavrogordato,¹⁶ Pancoast and Pendergrass,¹⁶ *et al.*) believe that following inhalation the particles of silica are engulfed by macrophages or "dust cells" which enter and block the lymph spaces. Mavrogordato¹⁶ concludes that silica kills the "dust cells" and dissolves in the alkaline tissue juices forming a poisonous hydrosol-jell ($\text{Si}(\text{OH})_4$). Gye and Kettle²⁶ have shown experimentally that colloidal silica when injected into animals is poisonous. Fibroblastosis is stimulated and a fibrotic nodule is formed about the dead macrophages. The center of the nodule heals and is free from silica; the periphery grows and abounds in silica particles. Confluence of these nodules produces a massive fibrosis in which are found nests of silica with contiguous healed lesions some of which show 1 mm. or less areas of degeneration. Few believe, with Arntzen,²⁶ that the physical characteristics (sharp edges) of the silica

particles are of much importance, although the presence of alkalis, concomitant infections, and rapid breathing undoubtedly predispose to silicosis.

McNally²⁷ reminds us that silica is a normal constituent of the human body but concludes that any lung containing more than 2 mg. of SiO_2 per gm. has had undue exposure to a dusty atmosphere. He found an average of 1.13 mg. of silica per gm. of dry lung in 21 samples from non-silicotic persons and reported from 2.4 to 26.0 mg. of SiO_2 per gm. of dried lung in workers in various dusty trades. Stone and granite cutters showed the higher amounts. Church²⁷ found the ash of potters' lungs to contain 47.78 per cent silica. In a study of 15 tunnel rock drillers and sand blasters and pulverizers, 12 of whom died of pulmonary infections within 9 to 18 months after short exposures, Gardner²⁸ found almost universally (all but one) microscopic but not gross evidence of silicosis. Sixty-one per cent of the bronchial lymph nodes were silicotic. The nodules ranged from 0.3 to 0.4 mm. in diameter as compared with 3.0 to 4.0 mm. sizes found in hard rock and lead miners with many years' exposure. A maximum of 3.1 per cent silica content in the lungs was found.

SYMPTOMS

As Russell²² points out, dyspnea, the earliest and the cardinal symptom, first sets in years after initial exposure and is progressive for years after exposure ceases. By the time shortness of breath is complained of, fibrosis already is moderately advanced, diminution in expansion and decrease in fremitus and resonance are demonstrable, and usually there is unproductive cough. Later the harsh breath sounds at the bases of the lungs become almost inaudible. Vital capacity is reduced. Cyanosis may be present. The anteroposterior diameter of the chest may be increased an inch.

The patient, however, remains well nourished unless tuberculosis complicates the picture.

The earliest roentgenographic findings are increased density of the hilus shadows and trunk branches, perhaps indistinguishable from the changes resulting from repeated respiratory tract infections. A diffuse increase in linear markings follows and in second stage fibrosis nodulation, most pronounced in the central and basal fields, is observed. Confluence of these nodules produces a picture of consolidation in third stage fibrosis in which pleural adhesions also are almost constant. An important prognostic sign is the fluoroscopic observation of limited excursion of the diaphragm.¹⁶

In the differential diagnosis it must be remembered that other dusts than silica, as well as other diseases, produce changes in the structure of the lungs, as pointed out by Pancoast and Pendergrass.²⁹ The writer has observed 1 case of advanced fibrosis of the lungs in a laborer who for 10 years had cleaned soot and lamp black from the stand pipes and gas purifier of a gas plant. The size of the heart shadow and the prompt disappearance of the lung shadows with restored compensation betray the passive congestion of cardiac decompensation and coronary thrombosis. In bronchiectasis the cough is not unproductive, and dilated bronchial shadows are disclosed by roentgenograms. In the asthmatic chest the mottling is accentuated during and immediately after attacks. Metastatic mycotic infections closely simulate the nodular phase of silicosis but isolation of the fungus and the clinical signs clear up the diagnosis. Diagnosis oftentimes will have to depend on post-mortem determination of the silica content of the lung tissues and the presence or absence of the ulceration and progressive destruction characteristic of tuberculosis.³⁰

Case 35—R. S., age 17 years, a caster for 3 years, had negative history and normal physical findings. X-rays (Plate I) revealed only slight peribronchial thickening and increased density in the hilar regions.

Case 54—M. P., age 32 years, a caster for 6 years, and coal miner for 10 years, had influenza 4 years previously, presented no symptoms and only slightly impaired resonance in the interscapular regions. X-rays (Plate II) showed moderate fibrosis, with diffuse peribronchial thickening and increased density of the hilar and perihilar areas.

REPORT OF STUDY

In the plant studied, bathroom ware exclusively is manufactured. The clay mixture contains 20 per cent silica, 26 per cent feldspar, 27 per cent English china clay, 10 per cent domestic china clay, 11 per cent English ball clay, and 6 per cent finely ground pitcher or broken ware. The free silica content approximates 20–25 per cent.

The casting room constitutes the essential dust hazard. Each caster must shake silica dust into, and dry-sand-paper and brush off the dust from his

own moulds. He is constantly inhaling silica dust and wears no mask. Occasionally the floor is sprinkled with water. There is no forced ventilation system. The fine dust which settles on the moulds while on the drying rack is blown off with a compressed air hose before the moulds go to the kilns. The dust produced by crushing and regrinding the ware broken during the first

Case 17—J. G., age 42 years, a caster for 10 years, had a negative history, symptoms and physical findings. X-rays (Plate III) revealed moderately advanced nodular fibrosis of the upper two-thirds of the lungs with dense hilar, perihilar and lower peribronchial shadows and diaphragmatic adhesions.

Case 34—J. S., age 48 years, a presser and caster for 27 years, had negative history, no symptoms, and had avoided inhaling dust when possible. Harsh breath sounds posteriorly, and a few coarse basal râles were heard. Fluoroscopy showed diaphragmatic adhesions. X-rays (Plate IV) revealed marked diffuse nodular fibrosis, with early massive confluence of the perihilar nodules.

Case 56—D. P., age 54 years, a potter for 21 years, had influenza 12, and right basal pleuritis 7 years previously. He had complained for 5 years of progressive shortness of breath and weakness, for 1½ years of dry cough, and for 2 weeks of inability to work as a foreman because of "smothering spells" (dyspnea), on the least exertion. He had lost 20 pounds in 2 years. Expansion of the chest was decreased; resonance was impaired in the interscapular and basal regions where dry coarse râles were heard. Breath sounds, harsh throughout, were distant at the bases. Fluoroscopy showed restricted excursion of the diaphragm. X-rays (Plate V) revealed advanced nodular fibrosis with massive confluence in the central and right basal fields.

This patient was awarded total and permanent disability pension by the Industrial Accident Commission of California.

firing, constitutes an additional hazard.

One hundred and six employees, exclusive of the office workers, were examined physically. In 58, with an average duration of exposure to silica-laden air of 7½ years, X-rays of the

Case 25—H. G., age 43 years, a caster for 12 years, had negative history, no symptoms or abnormal physical findings. X-rays (Plate VI) revealed marked diffuse nodular fibrosis with early massive confluence in the perihilar and inner basal fields. Death occurred 3 months later from respiratory failure 2 days after catching cold at his work. At autopsy were found healed apical (tuberculous) scars, dense, pleural adhesions, streaks of scar tissue scattered throughout both lungs, several small abscesses in the base of the left upper lobe, and scattered small bronchopneumonic consolidations.

chest were taken. As indicated in Table I, 5, or 8.6 per cent, showed third stage or advanced fibrosis, the average duration of exposure being 16 years. Twenty-two, or 38 per cent, had second stage or moderate fibrosis. The remaining 31, or 53.4 per cent, showed only slight fibrosis. In 5 of these latter the changes were confined principally to the hila.

TABLE I

PNEUMOCONIOSIS (SILICOSIS)

Incidence in 58 of 106 Pottery Workers as Determined by X-rays of the Lungs
(Quaintance-Morris)

Stage of Silicosis			Number	Per cent
Third *	Markedly advanced	3	5	8.6
	Moderately advanced	2		
Second	Moderate	22	22	38.0
First	Slight	26	31	53.4
	Hilus only	5		
Total			58	100.0

* Average duration of exposure was 16 years in advanced group.

Case 25—Early peribronchial fibrosis with siliceous deposits at outer margin. Plate VII.

Case 25—Early nodular fibrosis with many fibroblasts and silica particles at periphery. Plate VIII.

Case 25—Advanced silicotic nodules with beginning massive fibrosis. Note heavy peripheral siliceous deposits. Plate IX.

Case 25—Advanced, nodular silicosis, with marginal emphysema. Note sparsity of silica particles. Plate X.

Pancoast and Pendergrass¹⁶ in a study of 58 potters, reported third stage silicosis in 36 per cent, second stage changes in 48 per cent and first stage

silicosis in only 16 per cent. The average duration of exposure to dust in their series was not given, hence no accurate comparisons can be made.

Case 25—Contiguous, advanced silicotic nodules, with adjacent atelectasis and emphysema. Note absence of siliceous deposits. Plate XI.

TREATMENT

Since the nature of silicosis precludes the possibility of arrest of the progressive fibrosis it is obvious that our efforts must be directed at prevention:

First, reduction of the concentration of silica dust in the inspired air is imperative. Adequate exhaust ventilation equipment will replace dusty with clean air. Wetting will eliminate dust in grinding and mining operations and settle the dust in blasting rooms before workers enter. Chilled iron shot can be substituted for sand in blasting. Enforced wearing of adequate respirators and helmets and proper provision for their supervision and maintenance will protect workmen in occupations where wetting is not feasible.

Second, selective employment will result in the transfer of the unfit to less hazardous occupations. Preemployment examinations, including careful occupational history and record of past diseases, complete physical examination and X-rays of the chest, will make possible exclusion from hazardous occu-

pations of those having had excessive exposure to silica dust (Sappington³¹) and will keep the tuberculous out of dusty trades. Todhunter and Dixon³² suggest acquainting employees with the risks so that they may be educated in self-protection.

Progress is being made. Preemployment and interval examinations by a board of 3 medical examiners are required in Australia, South Africa, Great Britain, and Ontario. Wisconsin, New York, Oklahoma, and Ontario (Sayers³³) have attempted by legislation to limit the concentration of dust particles in the air which workmen must breathe to 10,000,000 per cu. ft.—the silicosis hazard threshold. If silicosis is to be controlled employers must be convinced that these preventive measures not only protect the health of their employees but are economically sound policies from the standpoint of industry.

COMPENSABILITY

Pneumoconiosis is regarded universally as an occupational disease. It is recognized as cause for total and permanent disability pension. In California under recent decisions of the Appellate Court with concurrence of opinion by the Supreme Court, the "date of injury" with respect to operation of the "statute of limitations" is regarded as the time of onset of symptoms or that time when the presence of silicosis could reasonably have been determined by medical examination of the applicant. Where more than one compensation insurance carrier is concerned, the Industrial Accident Commission has been ordered to apportion the liability for compensation as the duration of employment or the periods of insurance coverage would indicate as being equitable.

SUMMARY AND CONCLUSIONS

1. Inhalation of silica laden air results in pneumoconiosis, a progressive, incurable occupational disease of the lungs.

2. Fifty-eight cases are reported from the pottery industry in which the concentration of dust is low, silicosis develops slowly, symptoms are latent and appear many years after physical and X-ray signs of silicosis are demonstrable.

3. In advanced silicosis total and permanent disability for work, and a high susceptibility to pneumonia and tuberculosis are being recognized by the Industrial Accident Boards. Tuberculosis was not observed clinically in the group studied; pneumonia terminated 1 case.

4. Prevention of inhalation and reduction in concentration of silica laden air must receive more attention from the industries concerned, state legislatures and the medical profession if silicosis is to be controlled.

League of Mental Hygiene in Brazil

THE National League of Mental Hygiene of Brazil, according to its recent report, has been giving most of its attention in the 10 years of its existence to a campaign against alcoholism, to physical examination of persons intending to marry, particularly men, and to child guidance work. The child guidance clinic established by the league is working with mentally retarded or

otherwise mentally abnormal children in some of the public schools of Rio de Janeiro. Each child is given a thorough physical and psychological examination, and a written report of his condition with the necessary advice is presented to the parents. The results of this work are highly praised in Brazil.—*Arquivos Brasileiros de Hygiene Mental*, Rio de Janeiro, 6, 4, 1933.

Salmon Inspection*

RAY W. CLOUGH, PH.D., F.A.P.H.A., AND ERNEST D. CLARK, PH.D.
Northwest Branch, National Cannery Association, Seattle, Wash.

THE salmon has been a much appreciated article of food for untold centuries. Its bones have been found in the kitchen middens, or waste piles, of many forgotten peoples and some 10,000 years ago an unknown artist left us a record of this fish rather skillfully engraved on a piece of reindeer bone. This pictured fragment of bone, dug from the ashes in the floor of a cave in central France, shows that the salmon was valued by prehistoric men when the reindeer, following the retreat of the great glacial ice sheet, roamed throughout that section. Some of the earliest written records of the British Isles and Northern Europe have to do with fishing rights and "laws anent the saumon"; while early explorers along the shores of both the Atlantic and Pacific Oceans, north of the 40th parallel, found the natives depending largely upon this nutritious fish.

The salmon is an anadromous fish, that is, it requires both fresh and salt water for its complete life cycle. First seeing the light of day in some clear cool mountain streamlet or lake it spends a varying period of time in fresh water and then slips out into the sea, where food is more abundant, and growth is rapid. Arriving at maturity the salmon returns to fresh water to lay and fertilize its eggs, providing for the next generation. This spawning migra-

tion brings the fish together in great schools and makes their capture easier. In earlier times, this migration of mature salmon produced alternate periods of feast and famine, and various methods of preservation were developed to take advantage of nature's bounty and to ward off want as long as possible. Drying and smoking were probably the first preservative methods practised, and early records tell of extensive trafficking in salt salmon, while ice for the wider distribution of fresh salmon came into use about 1780. However, salmon did not become a world food, available in every important market, until after 1864 when the comparatively new method of food preservation known as canning was first employed.

From the Sacramento River in California, and a pack of a few hundred cases, the new industry spread to the Columbia River, Puget Sound, British Columbia, Alaska, Siberia, and Japan, and a yearly pack of some 9 million cases. A standard case for statistical purposes consists of 48 1-lb. cans or the equivalent, 96 ½-lb. cans or 192 ¼-lb. cans. The first small crudely built cannery on a scow has been replaced by hundreds, ranging in size from plants capable of canning a few hundred cases a day up to those that can pack 8,000 or 9,000. Some of these are poorly built and equipped, others are models of efficiency and design, splendidly equipped and scrupulously clean.

The salmon known to the artist cave-man, to Izaak Walton, the enthusiastic angler, to Spenser, Dryden, Shakespeare,

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

and other early British writers, was the Atlantic salmon, *Salmo salar*. This fish is still found in many of the rivers emptying into the Atlantic Ocean north of the 40th parallel and furnishes considerable sport for fishermen and a small amount of fresh and frozen salmon for an appreciative market. Practically none is canned. All of the canned salmon of commerce is supplied by the closely related Pacific salmons of which there are 5 species, all belonging to the genus *Oncorhynchus*. These are: *O. tshawytscha*, chinook, spring or king salmon; *O. nerka*, sockeye, red, or blue-back salmon; *O. kisutch*, silver, coho or medium red salmon; *O. gorbuscha*, pink salmon; *O. keta*, chum or keta salmon. The steelhead, *Salmo gairdneri*, although a trout, is occasionally packed as a salmon but forms only 0.3 per cent of the world's pack.

The most striking biological difference between the Atlantic salmon and the Pacific salmons is that all of the latter die soon after spawning, while, with good fortune, the former return to salt water to recuperate and may live to spawn several times. In this respect the steelhead resembles the Atlantic salmon.

DECOMPOSITION

The salmon, like other fish, being buoyed up by the water in which it swims, does not need as firm a structure as that required by land animals. Consequently it is more loosely put together with less connective tissue and while this contributes to a greater degree of digestibility of the flesh than is the case with meat, it also renders the fish more susceptible to damage by roughness in handling and to those decomposition changes leading to spoilage. It is imperative, therefore, that salmon should be handled with great care and canned, or otherwise preserved, as quickly as possible in order that deterioration may be kept at a minimum.

The term decomposition includes all of the changes that take place in the fish whereby it is broken down into its simpler substances. These may be due to enzymes secreted by the salmon itself, under control during the life of the fish but capable of digesting its tissues after death, or the changes may be due to the activities of bacteria. The muscle of the living salmon is practically always free from bacteria^{1, 2} but on the outside and in the gills, mouth, and digestive tract of the feeding fish there are large numbers of them. When the salmon is well started on the spawning migration it ceases to feed, the digestive tract shrinks and in most cases becomes sterile.² Feeding salmon should be cleaned immediately after catching while those that have ceased feeding may be safely left in the round for a few hours.

Any conditions of handling or storing which tend to increase the activity of the enzymes or to introduce bacteria into the flesh should be eliminated or prevented to as great an extent as possible. Rough handling, bruising the flesh, even though it may not break the skin, will increase the activity of the enzymes, further loosening the tissues and preparing the way for a more rapid invasion of the bacteria. Any breaks in the protective skin naturally permit the entrance of bacteria into the flesh. Temperature has much to do with the rate of activity of both enzymes and bacteria, so that during warm weather fish must be handled more carefully and rapidly than during cool weather.

DETERIORATION DURING SPAWNING MIGRATION

After the migrating adult salmon ceases to feed, it necessarily lives upon its stored up fat and protein. Work done by Green³ showed the effect of this spawning migration fast very strikingly in the disappearance of fat globules from within the muscle fibers

and changes in the fibers themselves. Certain Russian scientists⁴ made a very thorough study of the changes that took place in the Amur River chum salmon between the time some of them were caught in the open sea just as the migration started and those taken on the spawning beds as they were perishing. Some 97 to 98 per cent of the fat and 57 per cent of the protein was expended. Unpublished work by Shostrom (of this laboratory) shows a change in the average fat content of the pink salmon caught in one trap in Southeastern Alaska during the fishing season of 1930 from a maximum of 9.88 per cent to a minimum of 4.30 per cent. These fish were still in salt water with a long journey to the spawning beds ahead of them. There are other changes such as a softening of the texture, a bleaching out of the color of the flesh, and an abnormal coloring of the skin that take place during the migration. Naturally those fish taken early in the migration are superior in quality to those taken later.

Changes that have taken place in the fish due to deterioration during the spawning migration, to rough handling or to decomposition, all leave their marks on the canned product which can be detected and interpreted by the trained examiner.

INSPECTION OF CANNED SALMON

The more progressive canneries make a practice of examining some of the cans from each day's pack in order to correct any faults that may have crept into their methods, and those following this practice conscientiously seldom have trouble with their pack later on.

After the salmon pack is put up, it may be examined by one or more of several different agencies or organizations; governmental, trade associations, buyer or buyer's representatives. Of these groups the first is usually interested only in the condition of the

fish from the standpoint of freshness or in misbranding; the other groups are also interested in quality and in workmanship.

GOVERNMENTAL INSPECTION

United States—The federal government has, for many years, taken a very active interest in canned salmon. The Food and Drugs Act of 1906, as amended, established very definite and rather sweeping principles for the regulation of interstate traffic in foods and drugs. Some 80 per cent of the total American pack of canned salmon is produced in Alaska, a territory. Most of that produced in the coast states of Washington, Oregon, and California is shipped elsewhere for consumption and so becomes subject to federal regulation.

Government inspectors visit as many of the salmon canneries in Alaska and in the states during the packing season as their limited personnel and the great distances to be covered permit. They also draw samples from some of the parcels in interstate shipment for examination, which is confined for the most part to a determination as to whether any of the provisions of the Act have been violated.

Section 7 of the Act states that a food shall be considered adulterated "if it consists in whole or in part, of a filthy, decomposed, or putrid animal or vegetable substance." Literally construed this provision is very sweeping. The misbranding provisions of the Act require that none of the statements made on the label shall be "false or misleading." The Act does not require that the species of salmon be named on the label but the Code for the Canned Salmon Industry makes this mandatory. The net weight amendment of 1913 provides that all foods in package form shall bear a clear statement of the net contents and a regulation issued under the McNary-Mapes amendment of 1930

requires that the can be reasonably well filled.

The states and many municipalities have food laws and regulations, largely modeled upon those of the federal government.

Canada—The Dominion Government passed an Act in 1907 known briefly as the "Meat and Canned Foods Act." An Order in Council of April 4, 1932, created a Board of Inspection whose duty it is to examine all canned salmon packed within the Dominion. This board is composed of 3 men, trained in the examination of canned salmon, who inspect and report upon the quality and condition of the various parcels. If found "to be fresh, firm, well packed, and in good merchantable condition," it is approved and a certificate to that effect issued to the canner. Canned salmon found "to be sound, wholesome, and fit for human food," but failing in some respect to quality for a certificate is marked "Second Quality." This legend is embossed on can ends which are clinched on over the original end or ends, so as to conceal the word "Canada" usually embossed thereon. Canned salmon found "not to be sound, wholesome, and fit for human food," is confiscated and either destroyed or used by the Department of Fisheries in the feeding of small fish at the hatcheries and rearing ponds.

The law also requires the code marking of all cans in such a way as to show the species of salmon, the date of canning, and the name of the packer. The "first letter of the code marking shall represent the species as follows: Sockeye S, Pinks P, Cohoes C, Chums K, Springs T, Bluebacks B, Steelhead trout H." (The blueback in Canada is an early run of coho instead of a red salmon as it is on the Columbia River.)

Japan.—The Japanese Government maintains a supervision over the quality of canned salmon intended for export, and under its auspices the Japanese

Salmon Cannery Association, to which all salmon canners must belong, was organized in 1931. The association at its 8 inspection stations conducts a strict inspection in accordance with regulations issued by the Ministry of Agriculture and Forestry. Inspection is made of the outward appearance of cans and cases and of the contents.

The regulation further stipulates that after the examination, canned salmon is to be classified into 3 classes, namely, Passed, Non-exportable, and Rejected. The passed goods are further classified into 3 grades: First Class, or Choice; Second Class, or Standard; and Third Class. The first 2 classes may be exported to any part of the world, the third used only in Japan and a few specified countries. Rejected goods may not be sold anywhere.

EXAMINATION BY BUYERS OR BUYERS' REPRESENTATIVES

From the beginning of the industry it has been customary for the prospective buyer to demand samples for his own examination. While this is still done in some instances, it has become general practice for the buyer to rely upon the examination of some third party. Large buyers frequently have their representatives, living in the principal centers of production, who know what the buyer desires and make the examinations for him, selecting for shipment such parcels as meet his requirements. Smaller buyers, whose volume of business does not warrant a special representative, frequently rely upon the experience and judgment of public examiners for an impartial inspection of parcels in which they may be interested.

EXAMINATION BY TRADE ASSOCIATION

While the actual examination of canned salmon in Japan is performed by representatives of their trade associa-

tion; it is made under government supervision and is, therefore, virtually a government examination. The Canned Salmon Section of the Canadian Manufacturers Association is a voluntary organization and does not include the examination of canned salmon among its regular activities. The Association of Pacific Fisheries and the Northwest Salmon Cannery Association are voluntary American trade associations having offices in Seattle and comprise within their membership practically all the salmon cannerys operating in the United States and Alaska. They do not, however, include the inspection of canned salmon among their regular activities.

The National Cannery Association was incorporated in 1907, and in 1919 established an office and laboratory in Seattle, later known as the Northwest Branch. An office and general laboratory are maintained at 826 Skinner Building, and a canned salmon laboratory at Pier 40. The laboratory has spent much of its time in the examination of canned salmon. One of its first activities was a comprehensive study⁵ of the changes that take place in salmon during the early stages of decomposition. Salmon of each of the 5 species were taken alive from traps and held under cannery conditions, as far as possible, for several days. Each day some of the fish were subjected to detailed physical, chemical, and bacteriological tests, and then canned. Afterward the canned product was carefully examined physically, chemically, and bacteriologically, and the results were correlated, so far as possible, with the condition of the fish before canning. It was found that the quality of the fish as caught and the conditions and methods of handling were reflected very closely in the quality and condition of the canned product. Various other experimental packs have been made since to clear up certain points in the correla-

tion between the raw fish and the canned product.

Partly as the result of these studies, partly from the rather complete records of the examination of several thousand cans of salmon, and partly from the experience of several commercial examiners, a systematic method for examination was evolved.⁶ This has been modified slightly from time to time, but in principle has not been greatly changed. While the commercial examiners and buyers' representatives do not follow this method in detail, they do look for many of the same significant factors of quality and condition, and it is apparent that a considerable degree of uniformity in the method of examining has been attained. This uniformity is being promoted most actively, perhaps, through the Annual Canned Salmon Cutting Demonstrations where samples of all species, and from all American packing districts, are opened and judged by committees made up of men actively engaged in the production and merchandizing of canned salmon. It is, of course, highly desirable that all persons employed in this inspection should use the same general terms in speaking of the significant factors and should evaluate these factors on a fairly uniform basis.

EXAMINATION OF CANNED SALMON

The method in use by this laboratory will be outlined in order to bring out the significant points to be considered. Canned salmon is shipped, warehoused, bought and sold in blocks or parcels, varying in size from a few cases up to 50,000 or even more. The first step in the examination of a parcel is to obtain a very complete description of it, including the packer, cannery, species, brand, size and kind of can, can or code marks, number of cases, location in warehouse, etc. Careful attention to detail is frequently of great importance.

SAMPLING

An attempt is made to draw as representative a sample as possible, including all the different code marks to be found in the parcel. The sampling schedule calls for 12 cans (1 from each of 12 cases) in a parcel of 100 cases, 36 cans from 1,000 cases, 144 cans from 10,000 cases, etc. While the sample cans are being drawn the general condition of the parcel is also noted.

EXAMINATION

The examination of the sample cans covers:

1. Bacteriological and microscopical examination
2. Workmanship in packing
3. Quality of the fish when caught
4. Condition of the fish when packed
5. Chemical examination

Routine examination does not include the first and fifth of these divisions. Under special conditions these are sometimes employed however.

BACTERIOLOGICAL AND MICROSCOPICAL EXAMINATION

By the use of appropriate culture media, tests are made to ascertain if the cook used was sufficient. If spoilage has occurred in the parcel a bacteriological examination is desirable. By a direct microscopic examination and bacteria count, considerable information can be gained as to the condition of the fish when canned. The microscope has been used also to aid in the identification of the species of salmon through a study of the scales, which carry a record of the age of the fish when caught.

WORKMANSHIP IN PACKING

Under this head are included the evidences of all those fishing and cannery operations the effect of which may be observed in the canned product. Bruises and pugh [one-tined fork] marks, evidences of rough handling, are shown by blood clots and discolored

areas. The fish should be clean and free from all waste parts. It should be well placed in the can and consist of only 2 or 3 pieces. A proper cook is indicated by a rather soft and friable bone. A definite slightly salty taste is required to bring out the full flavor of the fish. Cans must be reasonably well filled, and the net weight equal to the amount stated on the label. They should possess a vacuum at sea level of 6 or 8 inches of mercury, as shown by a suitable gauge, in order to maintain a normal appearance if shipped to a warm climate or a high altitude. Cans having little or no vacuum may become "springers or swells," and thus unmerchantable, under these conditions.

QUALITY OF FISH WHEN CAUGHT

Each of the 5 species may range from very good to very poor when caught. This difference is due at times to a variation in the available food supply in the different sections, but usually, however, to the stage of the spawning migration. The examiner must take into account the characteristics of the different species in judging the color and texture of the flesh and the amount of free oil in the can. The oil is measured in cubic centimeters and compared with a standard chart based on the examination of some 79,000 separate cans in 1933. During the spawning migration the normal color gradually fades out, the texture softens, and the fat, from which the free oil comes, grows less.

CONDITION OF THE FISH WHEN CANNED

Under this head are included all the factors to be observed in a can which are noticeably influenced by the condition of the fish as concerns freshness, or lack of it, when canned. Fish are very delicate, easy to injure, and decompose very easily. Many opportunities for spoilage between the catching and the canning exist, and the excellent

condition in which the bulk of canned salmon reaches the market speaks well for the care and resourcefulness of the average packer. Much can be learned of the condition of the fish when canned from the odor, texture, "reddening" of the flesh, "honeycombing," and turbidity of the liquid.

The odor is the most generally applied and, perhaps, the most reliable test for decomposition or lack of freshness. The sense of smell is not equally developed in all people, and considerable experience is required before one is qualified to pass upon the odor of canned salmon. An abnormal "feverish" or reddened, appearance of the flesh is sometimes found, and occasionally little pits in the flakes which may extend entirely through them ("honeycombing"). These conditions are both due to the activity of bacteria and are not common. The liquid is always somewhat turbid but decomposition increases the turbidity, and when advanced may cause a milky appearance.

CHEMICAL EXAMINATION

In certain instances a chemical examination may be made of the contents of the can to detect the presence of certain products of decomposition, but such tests are slow and not adapted to routine analysis.

APPLICATION OF THE ABOVE SYSTEMATIC METHOD OF INSPECTION

While this method in substantially its present form has been used by this laboratory for some 12 years it was not until the 1933 packing season that it was tried out on a large scale. During that season the entire pack of some 46 different canning companies, totaling over 4,000,000 standard cases, was given a very thorough examination. There

were about 2,300 separate parcels upon which separate written reports were made covering workmanship, quality, and condition. Over 93,000 individual cans were opened and the can and contents examined. Whenever a single tainted can was found additional samples were taken from the parcel, and if further bad cans were found amounting to as little as 2 per cent of those in the parcel or code mark affected, the parcel or code was "reconditioned" by removing all of the stale or tainted cans. To do this each can in the parcel or code was opened and the bad ones destroyed. The good cans were closed and re-cooked. Only a few lots were found to contain bad salmon. Two small lots were destroyed due to poor seams on the end of the cans.

On the whole, the salmon pack for 1933 was found to be very satisfactory. This inspection was, perhaps, the most extensive ever carried out on any single food commodity. The packers co-operated whole heartedly and an even larger number have requested an examination of their entire 1934 pack, so that it is estimated that some 6,000,000 cases will be inspected by the laboratory this year.

CULTURES IN THE DIAGNOSIS OF TUBERCULOSIS

FROM England comes a report,¹ giving methods which if proved to be practical in general use, as they seem to be, should revolutionize the diagnosis of various forms of tuberculosis as far as the finding of the specific organism goes. The method originated in the Tuberculosis Department of the State Serum Institute, Copenhagen, at the hands of K. A. Jensen, who devised the culture medium which has been so successful. It is apparently a modification of that used by Lowenstein in his remarkable work.

The English report is the result of about a year of work. The writer, as Assistant Medical Superintendent of the Wooley Sanatorium, has had abundant opportunities to obtain material. She attributes her success not only to the culture medium but to the use of the screw-topped bottle in place of the customary test tube.

From the middle of September, 1933, to the middle of February, 1934, she has obtained positive cultures from some 250 specimens which were microscopically "T. B. Negative." The majority of these were sputum, but pus, urine, cerebrospinal fluid, and pleural fluid also gave positive cultures, often luxuriant. Apparently there is no more difficulty in cultivating tubercle bacilli of bovine type than those of human, though the characteristics are entirely different. It is said, however, that the human bacillus passes through a stage in which it is not distinguishable from the bovine. In profuse growths and prolonged incubation, the bovine colonies acquire color and lose their original smooth, shiny character.

In Denmark, Jensen at first confirmed his cultural findings as to type by the inoculation of rabbits, but later discontinued this when the growth was typically human, but continued it with bovine organisms. Holmes feels that with the growth obtained on her medium—a slight modification of Jensen's due to drugs furnished in England—and the screw-topped bottle, the differences are so clearly brought out that bovine cultures may be typed by this method alone, as in only 2 or 3 per cent is any difficulty found.

The author gives directions for making the culture medium, but believes that

there should be a central supply in each district for the use of general hospitals, sanatoria, tuberculosis clinics, etc. In addition to positive findings in doubtful cases, she believes that there is great value from the administrative standpoint, especially in regard to the infectivity or otherwise of tuberculous patients. Since positive cultures have been obtained in over 50 per cent of so-called "negative" sputa, she holds that such persons are at least as often as not infective to others.

Another point of importance concerns the transference of types of infection from one patient to another. The case is cited of a woman who was placed in a three-bed cubicle with two pulmonary tuberculosis patients. The physician in charge finally classed her as non-tuberculous and moved her to a "clean" ward, where she developed pulmonary disease. Examinations of sputum obtained by stomach washing gave positive cultures of bovine tubercle bacilli. It was then found that one of the two other patients in the cubicle had bovine phthisis. This is apparently the first case of infection from man to man with the bovine tubercle bacillus.

If sanatoria and laboratories generally are able to duplicate these results, the origin of the infection in many obscure cases will be cleared up. We will have at hand a method which should aid greatly in the fight against the spread of tuberculosis.

BAILEY K. ASHFORD

IN 1898 when the American Army invaded the then Spanish Island of Puerto Rico there was in the Medical Corps of the Expeditionary Forces a lieutenant named Bailey K. Ashford. Ashford went through the campaign and after peace was concluded, remained in Puerto Rico off and on until his death on November 1, 1934.

His biography, *A Soldier in Science*,* gives a very interesting and readable account of his early years in Puerto Rico, and is one of the best descriptions of medical service in the World War which have yet been published. When he first went to Puerto Rico in 1898 the United States had very little conception of what we understand today as tropical medicine and it is largely due to the investigations of Ashford that the American medical profession and public became interested in diseases of the tropics. In his studies of hookworm anemia in Puerto Rico, Ashford threw light on a disease which previously had been shrouded in darkness. The disease had been studied in Egypt, in mines in Germany, and at the St. Gothard tunnel in Switzerland, but to the American public the subject was almost a closed book. Ashford's clear-cut demonstration of the hookworm as the cause of the anemia of Puerto Rico was so convincing that his leadership in tropical medicine in the Americas was established for all time. His investigations were followed by a program of control and, so far as possible, of eradication of the disease from the island to which he devoted his life. In traveling through Puerto Rico with Ashford it was amazing and gratifying to see how the people, not merely of the cities, but of the country districts, knew him personally, respected his unselfish interest in their welfare, regarding him in the light of a father and protector. Few medical men have ever exerted such a broad influence in improving health and social welfare in their communities as Ashford in Puerto Rico.

* For review see *A.J.P.H.*, Oct., 1934, p. 1085.

When the knowledge of his hookworm studies became available in the United States it acted as a stimulus to physicians on the mainland to review their own experiences with reference to this hitherto unknown disease with the astonishing result that studies patterned after Ashford's carried out in the southeastern states showed that we too had an unsuspected problem in tropical medicine within our own borders. The health departments and physicians in general in these regions took up the work throughout the South and it continues to this day, fortunately with the same success in its treatment and prevention that Ashford himself had experienced in the island.

During the many years of his life in Puerto Rico he acted as adviser to the Government in health matters. He was the main factor concerned in building up the School of Tropical Medicine in San Juan under the auspices of Columbia University and the Government of the island, and here he continued his work in the study of the anemias and of another troublesome disease of the tropics called sprue, to which he contributed many stimulating hypotheses regarding its etiology. The disease, as every one knows, is still more or less mysterious, but our interest in it and the progress which has been made toward its understanding is due in no small measure to the initiative of Ashford.

During his busy life in Puerto Rico he developed a considerable practice in general medicine, but more especially in surgery, and was highly esteemed by the Insular medical profession as a leader in medicine, as well as in public health.

In the death of Colonel Ashford the medical profession has lost a distinguished member and our fellow citizens of Puerto Rico have lost a lovable friend whose daily work was guided by a rare idealism. Dr. Ashford was a member of the A.P.H.A. from 1912 to 1924.

SEWALL AND ANTITOXIN

THE Michigan Chapter of the Delta Omega public health society was concerned last year in reviving interest in a pioneer research of Dr. Henry Sewall. It had photostatic reproductions made of a paper published in the *Journal of Physiology*, of the year 1887, Vol. VIII, p. 203, which reports experiments on the preventive inoculation of rattle snake venom. A bronze plaque was presented to the University of Michigan commemorating the work.

The importance of this early work has been suggested in part by requests of European visitors to see the rooms and equipment used by Dr. Sewall in his experiments. Unfortunately nothing of the sort remains except in the memory of Dr. Sewall and one or two other men now living.

It has been suggested that these experiments and the following sentence from Dr. Sewall's paper may be viewed as the foundation upon which the great development of antitoxin has been erected.

If immunity from the fatal effects of snake-bite can be secured in an animal by means of repeated inoculation with doses of the poison too small to produce ill effects, we may suspect that the same sort of resistance against germ-disease might follow the inoculation of the appropriate ptomaine, provided that it is through the products of their metabolism that bacteria produce their fatal effects.

Recent correspondence with Dr. Sewall resulted in several reactions of modesty and unconcern as to personal recognition, and this gives further evidence of his greatness as a scientist and as a man. "I had long ago made myself content with the thought that self-aggrandizement is the least worthy of all rewards of scientific research."

PUBLIC HEALTH EDUCATION*

"Darwin was not above writing in a popular vein; neither was Tyndall or Huxley. Sir Humphrey Davy delivered numerous popular lectures on physics. Michael Faraday gave demonstrations of his researches in electricity to lay audiences."

IAGO GALDSTON, in *Better Times*

What We Noticed at Pasadena—
Further observations at the 1934 annual meeting will be welcome. A Section officer sends these informal notes:

The luncheon on health education materials showed us one thing at least—that we are all children who like toys. The profound moral is: simple things amuse and entertain and attract attention—don't be too high-brow if you want to get over health education.

It was nice to meet our co-laborers of the West Coast. Health education problems and effective programs are the same regardless of climate. Query: Wouldn't one of Dr. Peter's Chinese parades do more good in an American city than tons of pamphlets?

In Pasadena we at last had a chance to see what Routzahn's show looked like when it was all spread out where we could get at it. Did you notice there was someone studying his material all the time?

Dr. Tonney did a fine job on the radio program. Perhaps he should be made an honorary member of the Health Education Section.

Some of the radio speeches, by the way, could have benefitted with a little health education technic: splendid material, packed full of facts, excellent for a professional audience. Did they register with the populace?

Did you see the 17th Century English proclamation in the exhibit at the Huntington Library? There was one on the use of clean materials for filling pillows and mattresses. Baltimore passed a similar law a few weeks ago. Maybe this is why Huntington Williams felt that progress in health education was about as rapid as the erosion of the Grand Canyon.

When are we going to codify our knowledge of health education technic? Do we need a "Standard Methods of Health Education"?

Institute Enrollment at Pasadena
—The Institute attendance originated geographically as follows:

States and provinces: Arizona, British Columbia, California, Colorado, Hawaii, Oregon, Utah, Washington . . . Alabama, Tennessee . . . Illinois, Michigan, Minnesota, Missouri, Wisconsin.

California cities: 34 cities from which came 1 registrant; 9 cities with 2 registrants, 4 cities with 3; 5 cities with 4; 2 cities with 5; 1 city with 8; 1 city with 9; San Diego, 12; Los Angeles, 30; with 21 unidentified.

Prevent Cancer Among Mothers—
That "mothers' best protection against cancer of the cervix of the womb" is "the repair of all injuries and irritations following the birth of a child, and semi-annual pelvic examinations," was urged at Pasadena by Mrs. George F. Becker.*

Mrs. Becker, who presented her paper before the Public Health Education Section, is connected with Dr. Joseph Colt Bloodgood's Clinic and Diagnostic Center, Baltimore.

Mrs. Becker said that

. . . if mortality from cancer of the cervix is to be decreased, the medical profession, the public health workers, the nursing

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

* Delivered before the Public Health Education Section, Sept. 4, 1934.

profession, the social worker, federations of women, state and local governments must all unite in a standard and continuous educational campaign.

Representatives of the local departments of health, with the aid of the social workers, and the Red Cross representatives, and with the governing authority, could provide clinics and literature for those mothers who cannot afford to have their own family physicians. Each community, no matter how small, has its clubs and societies, its Red Cross Chapters, its nursing organizations, and its county board of health. Through these units there should be no difficulty in conquering cancer of the cervix of the womb. The medical profession admits that the majority of people today do not reap the benefit of modern medicine because of fear, ignorance, and finances. Therefore, to meet the situation in each locality, city and state (and in some instances interstate), the endeavor to prevent cancer of the cervix should be carried on by the local organizations. These should include not only the medical group, but all women's organizations, men's organizations, schools and nurses' training schools.

Selling the Health Department—

At Pasadena a paper was read by Kenneth W. Grimley,* director of the effective Bureau of Health Education and Publicity of the Jefferson County Board of Health, Birmingham, Ala.

Mr. Grimley's title was "The Technique of Selling the Health Department to the public." By omitting "Technique" the title would have been more accurate for Mr. Grimley concerned himself with the attitudes of those who do health department publicity and their professional preparation.

Mr. Grimley emphasized that

. . . salesmanship demands that one believe. It requires that you who sell health really, honestly, believe in the possibility of preventive medicine; that public health is purchasable in truth. Superficially it may seem that further discussion of this point would be a waste of time. But actually many of those engaged in public health, including

some disciples of public health education, have but a faint faith in its achievements and possibilities. We have all encountered health officials to whom the words *public health* convey nothing beyond the routine exercise of a petty police power in return for daily bread. Obviously such persons will not be adequate salesmen of the cause they represent. But of such we can expect but little, and thus need not fear disappointment.

A much more serious tendency is that exhibited in recent years in higher and more exalted circles. There is present in the world leadership of thought today, a widespread attitude of more or less sterile, critical intellectualism. I would not deny that science itself is founded upon the attitude of challenge. But ships and shoes and wax for seals are not sold by intellectualism—by people anxious to appear commanding leaders of pure thought. When we have reached the point where whole sessions of this section are keyed to an attitude of questioning, critical limitations, doubt—we are trying to become just too scientific; too brilliantly intellectual. Things are sold, even public health, by an attitude of enthusiasm, of belief in their usefulness, their possibilities, their service to mankind. Regard with an air of superiority if you will, the verve of salesmanship. But if your mind is too splendid an instrument to dig ditches through the mud of ignorance, by all means withdraw from a defiling task. To sell public health, you must believe. You must believe in public health. You must believe in its high promise that some day infectious disease shall be banished from the earth. You must believe that some day, through its wise administration, the crushing load of diseases, ill health, physical handicap, premature death, shall be removed and all mankind shall enter into that heritage of life abundant which is the promise of civilization.

Then of course the publicity worker must know public health.

Public health publicity is rather obviously a union of two distinct skills, or technics, or sciences; that of public health on the one hand, and of publicity on the other. Both of these fields are the domain of experts, of professionally skilled craftsmen. The selection of personnel to perform the joint task of public health publicity is thus not easy. It is a task so difficult, in fact, that it is usually but half done; that is, a person is selected who is entirely competent in one branch, and rather sketchily equipped in the other.

Some public health officials in establishing

* Presented at a Joint Session of the Health Officers and Public Health Education Section, Sept. 5, 1934.

bureaus of divisions of public health publicity seem to have a feeling that of the two, a skill in publicity is more essential. Thus we find publicity services manned by individuals more or less well grounded in the field of publicity, but whose knowledge of public health is largely hearsay. . . .

. . . To sell a department of health is a much more involved procedure than the sale of a car or a washing machine.

Public health requires of its salesmen a knowledge of preventive medicine in the abstract; a knowledge of its traditions—of its glorious history of achievement—of the lives of that company of immortals in whose debt humanity will ever be. The glamour of the great victory against disease and death can never be told by one unfamiliar with its recorded pages, however well he may speak the common tongue.

To sell public health one must know it in the concrete example one is selling. A department of health—even a small one—is a complex, dynamic thing, with a history, with policies, achievements, defeats and victories, tasks done and undone, opportunities, unsolved problems, ideals to which men have patiently devoted lives.

"Free" but Not Free—Most references to "Free" in this department of the *Journal* mean that *single copies* are supplied to health workers *free*, or for return postage. A few readers are inclined to ask for copies for distribution to the public or to all teachers in a school. Insurance companies and commercial advertisers are about the only sources for securing free material in quantity. It seems hardly fair to expect local or state departments to supply material for distribution in other states or cities.

Do We Need a Dictionary?—Do we need a professional dictionary covering such terms as "principles," "technics," "philosophy," "fundamentals," and other rather common word symbols? Although they are accepted as having fairly precise meanings we had a feeling at Pasadena that the preciseness was in the mind of the speaker. Frequently it was doubtful that all the hearers read the same mean-

ing into what they heard. May this lack of a common meaning be a cause of confusion and what seemed to be muddy thinking in discussions?

Broadcasting in Manitoba—The Manitoba Department of Health, at Winnipeg, is broadcasting three times a week via station CKY:

Tuesdays at 4:30 P.M. alternating with

Wednesdays at 12:30 P.M.

Fridays at 4:30 P.M.

In October and November, 1934, were presented on Tuesdays and Wednesdays two series on "Present Health Problems" and "Changing Health Needs," and "Child Health Problems" on Fridays.

"Mr. Average Citizen," a dramatic series in which Mr. Average Citizen "visits health agencies in Manitoba to find out their purpose and work" will come on Tuesdays and Wednesdays through January, February, and March. On Fridays in January a "woman's club representative" will report a series of visits to women's organizations, telling what they are doing to promote health.

Fridays in the following three months will be devoted to "My Body and How It Works," a series of stories for older children to supplement school lessons in physiology and hygiene. The stories have been adapted with permission of the authors, Dr. W. W. Peter, Dr. O. Reisse and Mrs. D. W. Baruch, and Harper and Brothers.

What Have You?—From time to time we mention individual requests for specific types of material. Your responses to such requests usually aid intensive efforts which seem worth while to help along. The editor of this department would value carbon copies of replies sent. We would like to learn what is available on special subjects and for special uses. Please answer, and please send us carbon copies.

The chairman of the Public Health Committee of the Central Branch of the Chicago Y.W.C.A. writes:

In a recent study of the health of Y.W.C.A. members and students, it was found that the eight most prominent physical disabilities and conditions existing among these women were: thyroid, tonsils, dysmenorrhea, constipation, malnutrition, heart, foot trouble, and overweight.

We are doing a good deal of study on these subjects and are making plans to put over a program of detection, prevention and care of these conditions to the hundreds of women reached by the Y.W.C.A. I am interested in getting hold of promotional material on these subjects, particularly posters, and I am appealing to you for information as to where to go.

Please address Marcella River, 4901 Ellis Ave., Chicago, Ill.

Please send copies of health education material to Dr. H. V. Tilak, Bombay Presidency Baby and Health Week Assn., DeLisle Road, Bombay (11), India.

Journals of health agencies are invited by Jewish National and University Library, Jerusalem, Palestine.

Use Your Own Special Audience—Dr. William P. Brown has been writing on public health for a Catholic magazine or two. There he has a ready-made audience, more or less willing to read about public health when presented in the special setting to which this audience is familiar.

Thus Dr. Brown points the way to a simple extra bit of service open to practically all health workers and teachers. Connection with a lodge or club, church or educational group, or any one of our countless centers or—those having like interests, offers a medium for the health worker. The organs of these groups may have local or state, or even national circulation.

Health councils as well as individuals might well try to interest health workers in this idea.

For samples of what Dr. Brown has

written address him in care of State Education Dept., Albany, N. Y.

The Study of Public Opinion—Princeton University Press, Princeton, N. J., has issued "A Reference Guide to the Study of Public Opinion," by Professor Harwood L. Childs, with a preface by Edward L. Bernays. 105 pages. \$2.00.

There are several hundred reading references classified under main headings and numerous sub-headings. Each section opens with an introductory statement, and closes with "topics for further investigation."

Some of the chapter topics: "Leaders and managers of opinion" (biographical); "The development of organized opinion management"; "The technique of organizing pressure groups"; "Instruments of opinion dissemination"; "What is public opinion?" It is in no sense a manual on methods.

For most topics there is much more material than any one is likely to use, but it should be understood, as is pointed out by the author, that the references are uneven in value.

Under "The Press" there is no mention of *Editor and Publisher*, chief journal of the newspaper press. Critical magazine articles are almost all omitted; and the section on "The Trade and Periodical Press" is rather absurd in its inadequacy. "Present Status of Radio" overlooks magazine discussions in the past few years, and omits mention of National Committee on Radio in Education, probably the most important single source of critical material.

"Studies of Technique in Particular Fields" seems less inclusive than its general heading of "Strategy and Technique of Opinion Management." At least there are almost no critical or questioning references.

There is no sub-heading for "health," "social welfare," or "social work," but

under "Business" along with commercial advertising we find listed two books by the Routzahns!

Notwithstanding what is not there, the book is well worth having. It might be brought to the attention of various local groups having program sessions or discussion meetings.

What Editors Say—Many editorials on health and other welfare topics merit a wider audience and a longer life than comes with their original publication.

Some 46 editorials have been collected in "Editorial Opinion and Social Work," a 17 page pamphlet. Health is the subject of editorials from *Collier's*, *New York Times*, *Honolulu Star Bulletin*, *Miamisburg, Ohio, News*, and *Springfield, Ill., State Journal*. There are quotable sentences for use in your own copy. Editorial writers would be interested in seeing what others have written.

Issued by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 25 cents; special price for quantity.

Health Education in New York City—One of the few examples of community-wide consideration of health education is promised by the reorganized Health Education Section of the Welfare Council of New York City. The executive committee: D. B. Armstrong, M.D., Mrs. K. Z. Whipple, Savel Zimand, C. F. Bolduan, M.D., Iago Galdston, M.D., G. M. Galloway, G. T. Palmer, D.P.H., Marguerite A. Wales.

Jane M. Hoey is secretary of the Health Division, Welfare Council, and Valeria McDermott is Assistant Secretary.

What Is In Hygeia, November, 1934—Among the topics presented:

Foot twisting and faith healing . . .
Tuberculosis and the kings of France . . .
The story of local anesthesia . . . Pre-

venting arthritis . . . The parent, the dentist and the child . . . Prenatal care . . . Dainties for the diabetic . . . The myth of the average child . . . The body louse . . . Poisoning in industry . . . The doctors of Dickens . . . Selling vegetables to the family . . . The a b c of proper brushing . . . If your child is overweight . . . What you should know about eye-glasses . . . Dental dens (quacks) . . . Solving health educational problems . . . New books on health . . . Questions and answers.

NEW OR RENEWED

Bulletin, Mass. School Dental Assn., issued by Massachusetts Dept. of Public Health, Boston, Mass.

The *Monthly Bulletin*, Indiana Division of Public Health, Indianapolis, has been revived under editorship of Thurman B. Rice.

TEACHING OR TALKING

Health and education agencies through the New Jersey State Normal School at Newark are offering an accredited course in "Principles of Dental Health Education," by Dr. J. M. Wisan.

The Junior League conducted a Welfare Conference in Minneapolis, Oct. 15-19, 1934. Public Health was represented on the program by several round tables, addresses and field trips.

Three institutes on health education in secondary schools were conducted this fall by Massachusetts Tuberculosis League in coöperation with the State Dept. of Public Health.

WHAT AND HOW

"The Educational Objective of Public Health Nursing," by M. Lindeburgh. *Canadian Public Health Journal*, 105 Bond St., Toronto 2, Ontario. 35 cents. "How shall we educate or prepare the public health nurse that she in turn may educate the public?"

"Interpreting Health Education," by Ruth Ware, discusses Y.W.C.A. services in relation to association and community chest budgeting. It emphasizes

interpretation of the program to board members, association members, and "the community at large." *Womans' Press*, 600 Lexington Ave., New York, N. Y. Oct., 1934. 20 cents.

A sampling of health articles in *Red Cross Courier*: "How Safety Came to Civil Works"; "Adequate Schools Aid Development of Water Program at Home"; "Hospital Guild Sponsors Home Hygiene"; "Folk Lore Treatments Disappear When Case Worker Talks on First Aid"; "The Schoolhouse on the Hill" (country home hygiene class).

TO HAVE OR TO USE

A feature of the scientific exhibits at the American Medical Assn. and the American Public Health Assn. conventions was a series of charts reproduced in a pamphlet entitled "Progress in Public Health Since 1900," with an introduction by Dr. L. I. Dublin. Some titles: "Diphtheria a vanishing disease"; "Longer life for more people"; "The mounting death toll from cancer"; "Reducing the hazards of early infancy." Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y. 12 pages. *Free*.

An appeal for the support of private health agencies was issued Nov. 1 by Col. Theodore Roosevelt, president of the National Health Council. Although given out for immediate effect in the fall Mobilization for Human Needs the statement should be useful locally throughout 1934-1935 in money raising efforts. Address the Council at 50 West 50th St., New York, N. Y. *Free*.

"Children's Bureau and Other Publications Relating to Children." Price list 71 of government publications. Supt. of Documents, Washington, D. C. 15 pages. *Free*.

"A Directory of Organizations in the Field of Public Administration" is a 2d edition. Describes briefly 500

national organizations, public and private, including health and others of interest to health workers, and many others. There are listed more than 1,400 state, regional and Canadian associations. 192 pages; paper covers. \$1.00. Public Administration Service, 850 East 58th St., Chicago, Ill.

"The Need for a More Adequate Program of Maternal Care," by F. C. Rothert, M.D. Reprint. *Public Health Nursing*, 50 West 50th St., New York, N. Y. 10 cents.

"The School and Tuberculosis," by W. P. Brown. *Hygeia* reprint. Address author, State Education Dept., Albany, N. Y. *Free*. Adequate examinations and follow-up.

"Suggestions for Organizing a Community Social Hygiene Program." American Social Hygiene Assn., 50 West 50th St., New York, N. Y. 10 cents.

In *Milbank Memorial Fund Quarterly*, 40 Wall St., New York, N. Y. (Oct., 1934; 25 cents):

"A Project in Rural School Health Education," by Ruth E. Grout. The third paper by the director of health education in Cattaraugus County.

"An Organized Community Health Education Program," by Savel Zimand. Largely based on the Bellevue-Yorkville experience.

"Public Health in Rural Reconstruction at Ting Hsien, by C. C. Ch'en. Includes brief statement on health education.

Reprints from *Journal of Social Hygiene*, 50 West 50th St., New York, N. Y. (10 cents each):

"Social Hygiene Education in a City of Medium Size," by J. B. Pinney.

"Popular Health Education in Simplest Terms," by M. S. Edwards. Social hygiene education for Negroes.

"Milk for Men," and "Good Nutrition and Colds," in Dairy Council Digests, National Dairy Council, Chicago, Ill. *Free*.

"Sunkist Food Bulletins — 1935 Series." Calif. Fruit Growers Exchange, Los Angeles, Calif. For "food teachers and nutrition workers."

MAGAZINE ARTICLES

What do any of us do to call attention to any magazine articles we believe would be of value to staff members, or to other groups, or to the general public?

"Making School Lunch-boxes Appealing," by D. Kirk. *Literary Digest*, 354 4th Ave., New York, N. Y. 10 cents. Variety adds joy and health values.

"Better Food for the College Man," by H. Ripperger. *New York Times Magazine*. Sept. 23, 1934.

"Brevities of 1934." Editorial page. *Collier's*, Sept. 15, 1934. "We shall be a healthier, more vigorous people."

"California's Medical Mix-Up," by P. K. Brown, M.D. *Survey Graphic*, 112 E. 19th St., New York, N. Y., Sept., 1934. 30 cents. "Description of California's trials, mistakes and progress in putting essential medical care within reach of her citizens."

"Catholics on Birth Control," by G. I. Burch. *New Republic*, 421 W. 21st St., New York, N. Y. Sept. 5, 1934. 15 cents. "The crusade of the Roman Catholic Church against the birth-control movement has suddenly turned into a duel over methods."

"Sanctified Birth Control," by D. D. Bromley. *Nation*, 20 Vesey St., New York, N. Y. Sept. 26, 1934. 15 cents. The "safe period"; some of the evidence for and against.

"Birth Control and the Depression," by D. B. Bromley, *Harper's*, 49 East 33d St., New York, N. Y. Oct., 1934. 40 cents. Milbank and other statistics; unwanted children chief depression sufferers; medical profession and Catholic Church—both changing face.

"For Legalized Birth Control." *New Republic*, 421 West 21st St., New York, N. Y. 34 pages. 25 cents. The abortion problem; contraceptive devices and antiseptics; where to get advice.

"In Sickness and in Health," by K. Crichton. *Collier's*. Oct. 20, 1934. "Something is wrong. Millions of Americans are without medical care while thousands of doctors, dentists and nurses are without adequate incomes."

"Sound Facts about Constipation," by W. W. Bauer, M.D. *American Mercury*, 730 Fifth Ave., New York, N. Y., Oct., 1934. 50 cents. "Each man and woman should be a law unto himself or herself," and why.

"Sparing the rod," by J. Ruhrah, M.D. *Today*, 152 West 42d St., New York, N. Y. 10 cents. "Many of those who were raised by the rod have escaped both penitentiary and the hospital for the insane."

RADIO

Education by Radio will keep you in touch with the efforts to secure adequate broadcasting time for education and other non-commercial interests. The publisher is National Committee on Education by Radio, 1201 16th St., N. W., Washington, D. C. Will be sent free upon request.

"Second Series of Radiologs—Radio Talks on Preventive Medicine." Virginia Dept. of Health, Richmond, Va. 68 pages. Free. Topics range from "Adenoids" to "Why pioneers had no pellagra."

The fifth radio contest has been announced by Minn. Public Health Assn., 11 West Summit Ave., St. Paul, Minn. The subject: "Youth Takes a Look at Its Greatest Enemy." The awards: Gold medals to the authors of the 10 best manuscripts, and a trip to Minneapolis to broadcast the talks.

The Health Department of New York City carried on a series of summer health broadcasts for children, having asked the teachers and principals before vacation to tell the children about the radio series. As a special attraction, famous athletes were on the programs—Gene Tunney being the first.

BOOKS AND REPORTS

Symposium on Silicosis — *Trudeau School of Tuberculosis, Saranac Lake, N. Y., June 18–22, 1934. Wausau, Wis.: Employers' Mutuals.* 98 pp. Price, \$5.00.

This is a printed, but unofficial, transcript of the papers and discussions held informally in connection with the symposium referred to in the title. Several who attended the sessions, which were substituted for one week of the regular 1934 course in the Trudeau School, took elaborate notes and the present compend represents the collection and editing of same under B. E. Kuechle of the Employers' Mutuals. The galley proof was submitted to the various speakers to review and correct, which they did. The introduction was written by Dr. Leroy U. Gardner, Director of Saranac Laboratory.

The subjects covered and their authors include: The Etiology of Silicosis, by Dr. Roy R. Jones, U. S. Public Health Service; Dust Concentration and Methods of Measurement, by Donald E. Cummings, Saranac Lake; Pathology, Human and Experimental, by Dr. L. U. Gardner, Saranac Lake; Occupational History, by Donald E. Cummings; Clinical Aspects and Physical Findings, by Dr. Henry H. Kessler, New Jersey; Roentgenological Findings, by Dr. H. L. Sampson, Trudeau Sanatorium; Roentgenological Diagnosis, by Dr. H. K. Pancoast, Philadelphia; Engineering Methods of Prevention, by Prof. Philip Drinker, Harvard; Medical and Legislative Measures of Prevention, by Dr. A. J. Lanza, Metropolitan Life; Fibrosis in Lung Disease, by Dr. William S. McCann, Rochester.

In brief, the volume comprises the latest views of the specialists named,

each of whose informal papers is followed by a compact statement of the discussion which ensued.

Due probably to the nature of note-taking, some parts show much said in short, terse sentences so that the meaning may be ambiguous, but there is a wealth of valuable views and summaries of experimental facts, conclusions and observations. The comprehensive outline by Gardner on the pathology of the subject is superb and in itself may be said to condense volumes.

While there may be some comment about the price asked for this little volume, the entire proceeds are to be given to the Saranac Laboratory for research on silicosis—which, while probably the most definite of all afflictions of truly occupational nature, is today the most controversial as to cause, course, complications, and prognosis. Whence, carefully controlled work from an institution like Saranac should be awarded every financial support. The monograph is truly indispensable to any who are interested in the silicosis question.

EMERY R. HAYHURST

Mothers' Guide When Sickness Comes — By Roger H. Dennett, M.D., and Edward T. Wilkes, M.D. Garden City, N. Y.: Doubleday, Doran, 1934. 400 pp. Price, \$2.50.

This book, written by two well known specialists in diseases of children who have had a wide clinical as well as administrative experience, contains a wealth of information which every mother should have available. As stated in the preface, it is not intended to take the place of the doctor, but to aid in carrying out his orders.

The material is divided into four parts, Part I perhaps being the most useful as to the general information which the average mother should have. While all the chapters are good, we especially recommend those on sunshine and milk. Part II considers Infectious and Contagious Diseases, with a discussion on prevention and treatment of those which are incident to childhood. Part III is devoted to Other Common Ailments, such as prickly heat, ringworm, eczema, hives, ivy poisoning, thrush, etc. Part IV contains valuable instructions and advice for caring for the sick child, such as Common Practical Nursing Procedures, a Poison and Antidote Table, Special Diets, Weight-Height Tables, and a glossary. A good index adds to the value of the volume.

There is always some danger that mothers may carry the use of such a book too far, in spite of the warning by the authors that it is not intended as a substitute for the doctor. During times of depression, such as we are going through, this danger is more acute than usual. In view, however, of the delay in sending for a physician so often encountered even in cities where clinics abound, the sound advice given will doubtless aid many and even save lives.

The book is written in a pleasing style which is easily understandable. At the beginning of each chapter we find an appropriate quotation from well known and favorite writers. This excellent work can be heartily recommended and we wish for it a wide circulation. MAZYCK P. RAVENEL

The Biology of the Protozoa—By G. M. Calkin (2nd ed. rev.) Philadelphia: Lea & Febiger, 1933. 607 pp., 233 figs. Price, \$7.50.

This new edition of Professor Calkins' book has in it many features of value to workers in public health among which are the following: a

full account of the structure, life history, physiology, and reproduction of the protozoa; a chapter on parasitic protozoa of the vertebrates, especially of man, with colored plates of the three species of the parasite, *Plasmodium*, causing malaria; and a detailed account of the classification of the Protozoa with many illustrations of various kinds of Protozoa. No laboratory should be without this valuable source of information in this important field.

C. A. KOROID

The Family—By M. F. Nimkoff, Ph.D., under the editorship of William F. Ogburn, Ph.D. Cambridge: Houghton Mifflin, 1934. 526 pp. Price, \$3.00.

In view of the marked increase in courses on the family in colleges and the more general recognition of the important position occupied by the family in the social and economic reconstruction, a comprehensive treatment of this subject is timely. As the editor points out, the family has always been a major social institution and until recent times our chief economic unit. But the change which is taking place in family life is making it a different institution than formerly. The book is well balanced, filled with the latest scientific contributions, and clearly written.

The twelve chapters deal with the structure, functions, and early development of the family—biological, economic, and psycho-social aspects, including the child and the marriage relation, family disorganization and reorganization. Influences of colonization, of industrial revolution and of urbanization are considered. Chapters dealing with the biological and economic aspects will be of special interest to public health administrators. Problems of maternal and infant mortality, abortions and illegitimacy are briefly considered, as well as population changes. Students and teachers in several fields

will find this a very useful volume. To executives of health and social agencies, it should prove exceedingly helpful for reference purposes. IRA V. HISCOCK

La Lèpre—By E. Jeanselme. Paris: G. Goin & Cie, 1934. 679 pp. 259 figs. 14 col. plates.

Professor Jeanselme, who has contributed materially to our present knowledge of leprosy, has written a thorough-going treatise on leprosy which has appeared as a monumental volume published with aid of the French Government. It was not intended to be a complete compilation of the literature, for there already was such a work; it was to be more personal and critical. Nevertheless, the presentation is far from being dogmatic, and in fact it is sometimes difficult to ascertain precisely what the author's views are. Most questions are fully covered, with much attention to the literature, so that the book is replete with citations and footnote references.

The first of the 15 chapters, the definition of leprosy, covers but a half page. The second, a 4 page table of words signifying leprosy and related terms, is doubtless the most complete list of the sort yet compiled. The same assiduity of compilation is seen in the fourth section, on geographic distribution; it follows one on history, which, beginning with the Bible and earlier documents and coming up to the Manila and Bangkok conferences of 1930-1931, reflects the author's recognized historical bent.

Bacteriology, the first of the technical subjects, is dealt with in a comprehensive chapter in which the attempts at cultivation, held by the author to have been unsuccessful as regards transplants in series, are summarized in periods. The first of these, before 1900, is properly dismissed very briefly; of the most recent reports, those of Wherry (1930), and of Soule and Mc-

Kinley (1932) have been overlooked. A few pages on rat leprosy, based largely on the numerous reports of Marchoux and his colleagues, follow a discussion of the attempts to transfer the human infection to animals. Serology is dealt with adequately in view of the unsatisfactory status of the matter, but the section on immunity and allergy reflects the small amount of attention that has been given this aspect of the problem.

"General pathology" is a short chapter, but that entitled "anatomoclinical study," which covers both the clinical and pathological features, fills more than 200 pages. Illustrating them are a number of colored plates, most of them representing microscopic specimens, that are exceptionally fine. There is a long chapter on etiology followed by short ones on the evolution of the disease and prognosis. Diagnosis is given more space and prophylaxis much more. Treatment is a most important chapter. The author holds that there is no specific remedy but that amelioration, and perhaps cure, is possible by means of a course in which parts are taken by personal hygiene, care of complicating conditions, and special agents, the last referring particularly to chaulmoogra medication.

It is impracticable to attempt to set forth here more than a few of the author's views, but all of them are entitled to consideration. Unfortunate features of the book are, its size and weight—nearly 13 x 10½ inches over all, and weighing nearly 10 pounds—and the lack of an index, its place being occupied by a topical summary more appropriate for the front of the book. It would be unfortunate if these features, or its cost, should serve as deterrents to its general use, for it is a really valuable work and should be in all medical libraries and in the hands of all who are doing serious work in leprosy.

H. W. WADE

Benjamin Rush. Physician and Citizen, 1745-1813—By *Nathan G. Goodman*. Philadelphia: University of Pennsylvania Press, 1934. 421 pp. Price, \$4.00.

Doubtless many will be as surprised as was the author of this book, to discover that there existed no biography of Rush, in many ways the most distinguished of early American physicians—"The American Sydenham," as he has been called. The public and the medical profession owe to the author a peculiar debt of gratitude for the present volume, written some 120 years after the death of this distinguished man.

The work has all the earmarks of a labor of love. It is well documented and is a mine of information concerning the early days of our country, the Revolutionary War, and some of the master minds who laid the foundation on which the medical profession of America stands today—unsurpassed by any in the world. From the medical standpoint, the book is particularly interesting in its account of the epidemics of yellow fever in Philadelphia, especially the great epidemic of 1793. Though this led Rush into a bitter controversy, it shows him to have been a master mind. He apparently believed for some time in the contagiousness of yellow fever, but abandoned this idea and charged its origin to local conditions. This brought upon him bitter attacks, some even going so far as to declare him insane. His practice during the great epidemic was enormous. His treatment was bleeding and purging, an idea he obtained from Dr. John Mitchell, who wrote on the disease in 1744. He held that the lives of 6,000 Philadelphians were saved by this treatment. While we cannot accept Rush's ideas, "there was something heroic as well as deeply spiritual about his labors." On one occasion he said, "Thank God, out of the hundred patients I have visited or prescribed for this day, I have lost none."

Rush was a most remarkable man, and one wonders how he could engage in so many activities and show mastery in all. He was most interested in the abolition of slavery, the abolition of death penalty, and restriction in the use of alcohol and tobacco. He was president of one of the first cotton mills in America, in 1775, feeling it necessary on account of the embargo on the importation of British goods, to provide for the needs of Americans in this line. He was the founder of the first free dispensary, the first temperance and anti-slavery societies, the first Sunday School system, one of the founders of the College of Physicians, active in the foundation of Franklin and Marshall College and of Dickinson College. He was the first American psychiatrist and the first professor of chemistry, having been appointed in 1789 to that chair in the College of Philadelphia, completing the faculty of the first medical college in America. In April, 1777, he was appointed Surgeon General of the Medical Department of the Continental Army. Unfortunately, apparently owing to his friendship for Generals Gates and Conway, he became involved in the Conway Cabal. Wrong as he was, and though a bitter critic, he was a patriot and never a conspirator. He also was ruthless in condemning Dr. William Shippen, Director-General of the medical department.

Rush made some remarkable medical observations. He was among the first to recognize the relationship between infected teeth and arthritis, and in his treatment of chronic diseases, examined the teeth and extracted the decayed ones. He gives a number of cases in which severe systemic disease was entirely cured by getting rid of the focal infection. This was done approximately 130 years ago, yet the influence of focal infections is generally considered one of our recent discoveries due to bacteriology. It is most interesting also to

note his introduction of the Suttonian system of inoculating against smallpox, to which he attributed a great increase in his practice. This restricted the inoculation to a small puncture instead of the then popular long incision, and may be regarded as the distinct predecessor of the modern method of performing the Jennerian vaccination. However, as soon as Jenner announced his discovery, Rush became a convert.

We wish we were able to speak at greater length of this remarkable man, but the book must be read to obtain anything like a fair appreciation of him. We cannot do better than close with two quotations:

His character was laid upon foundations of integrity and service, and once he was sure within himself of the soundness and morality of his stand, he resolutely refused to compromise. He would not yield an inch even to gain a foot; and therefore he was doomed to meet defeat and condemnation many times when he deserved better. Furthermore, his candid self-righteousness only aggravated his adversaries and made him deaf to reason as well. It was a tragic contradiction of Rush's life that his stubborn individualism obscured the originality of his mind, the attractiveness of his personality, and the honesty of his motives.

Benjamin Rush was a leader in many fields: he was a great physician, a talented teacher, a competent scientist, an able organizer, a felicitous writer, a vigorous social reformer, an earnest philanthropist, a creative scholar, and a devoted patriot.

MAZŮCK P. RAVENEL

Diphtheria. Past and Present—*By J. Graham Forbes, M.D., Principal Assistant Medical Officer, London County Council; Late Milroy Lecturer, Royal College of Physicians. London: John Bale, Sons & Daniels-son, Ltd., 1932. 832 pp. Price, \$15.00.*

This monumental work has as its basis the Milroy Lectures of the Royal College of Physicians for 1929. There was considerable delay in publication, and many additions were made.

The book is a veritable encyclopedia of pretty nearly everything which science and experience have taught us concerning diphtheria—Etiology, Distribution, Transmission, and Prevention, each of which forms a section of the book. Much space is given to the distribution in England and Wales, which is of more interest to the inhabitants of the British Isles than to Americans though necessarily there is much in the survey which is applicable to many parts of the world. However, reviews are given of the situation in the United States, Canada, South America, and Germany, though the chief consideration of these surveys is preventive work. A conclusion sums up the matter in a very satisfactory way. This is followed by a good general index, a geographical index, and a list of the authors quoted, all of which make the book easy to use and will serve for the student as a source book.

During the past 2 years we have learned much about new materials for the prevention of diphtheria. Toxin-antitoxin, toxoid-antitoxin, toxoid-antitoxin floccules, and toxoid (anatoxin) are discussed. In America the alum precipitate is gaining ground rapidly. With this exception, the methods described, discussed and evaluated by the author are up to date.

The author is well known and his official position has given him unusual opportunity for mastering the subject of which he treats.

The book has an introduction by Sir Frederick Andrewes. The work is not only voluminous but every item is well considered and treated with the conservatism and sound judgment which characterize English scientists. It can be recommended most heartily to health officers, physicians in general, and all who are interested in the various phases of the diphtheria problem, though it is not suitable for popular reading.

MAZŮCK P. RAVENEL

Child Guidance Clinics—By George S. Stevenson, M.D., and Geddes Smith. New York: The Commonwealth Fund, 1934. 186 pp. Price, \$1.50.

One of the most interesting, though relatively unfamiliar developments of the 20th century has been the child guidance clinic. The average public health worker is somewhat at a loss to evaluate it. Hence this succinct story of the origin, development, and present status of the clinics, published by the Commonwealth Fund which has had such a large share in its life, is worth the reading by everyone interested in the progressive welfare movements of the day.

The book opens with an orienting chapter on child guidance. Then, after a chapter devoted to backgrounds, there is a discussion of the "pioneer clinics," in which, among that of others, Dr. Healey's work in Chicago and Boston receives sympathetic consideration. Chapter four is devoted to the story of the demonstration clinics conducted by the National Committee for Mental Hygiene and financed by the Commonwealth Fund. These are covered individually and in some detail, with special reference to the part each played in furthering the development of the child guidance principle.

The latter part of the book is devoted to what is called "the present pattern" and a discussion of Trends and Possibilities. This is the part which will appeal most to the general child hygiene worker since we all are interested in the future of this kind of approach to the problem of the child who may be headed for delinquency or mental disease.

The authors are eminently fair in their discussion of the possibilities of the clinic. They do not minimize its relatively large cost and limited facilities. They feel that "the hypotheses on which the child guidance clinics base

their program are still fluid"; hence the impossibility at present of offering definite rules for the instruction of the non-psychiatric worker. This is of course a sound position to take, though disappointing undoubtedly to many.

It would seem to be a fair conclusion that private agencies should continue to finance child guidance clinics during their experimental years, if not longer. One might venture the opinion that, in view of the relatively large staff and expense involved as compared with the relatively small group of children which can be handled effectively, these clinics for a long time to come should be thought of as laboratories and, perhaps, teaching centers rather than as clinics in the ordinary acceptance of the word.

MERRILL E. CHAMPION

Hygiene and Home Nursing—By Louisa C. Lippett, R.N. Yonkers, N. Y.: World Book Co., 1934. 424 pp. Price, \$1.24.

It is somewhat of a disappointment to find such attractive covers enclosing rather trite and unimaginative material and such well printed pages including information which is not quite up-to-date. The discussion of underweight and overweight does not consider the newer ideas of the importance of growth rather than comparison with a standard. Posture becomes in this book a matter of exercises rather than an evidence of good mental and physical health. The chapter on tuberculosis is scarcely complete since it leaves out the entire topic of tuberculin testing, regarding which it is especially important that lay people be informed. Soap is not mentioned as a disinfectant although far less simple and more uncommon disinfectants are suggested in the care of communicable disease cases.

We had hoped to find in such a textbook for high school girls interesting suggestions for finding information and trying out some new adventures in

health. Instead we find only good but prosaic questions at the end of each chapter and no suggestions for reference reading.

Many women and girls would find the terms confusing and would find difficulty in adapting some of the technics to the home. The book is written from

the standpoint of the graduate nurse rather than from that of the home maker.

The descriptions of anatomy and physiology are clear and quite interesting and could be used to supplement less simple material.

VIRGINIA A. JONES

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

What the Public Wants—Invited to send in questions to be answered in a radio health forum or in a newspaper substitute, the public showed its interest in disease rather than health. After many unsuccessful attempts to curb the appetite for information about pathological conditions, the question and answer method was dropped.

CHADWICK, H. D., and LOMBARD, H. L. *The Health Forum*. *New Eng. J. Med.*, 211, 17:767 (Oct. 25), 1934.

About Amebic Dysentery—The epidemiology of amebiasis differs little from that of other food and water-borne diseases. Important factors in successful epidemiology in this disease are the recognition of its prevalence and a thorough understanding of its nature and transmission. This is one of several excellent papers constituting a symposium on the subject.

CRAIG, C. F. *The Epidemiology of Amebiasis*. *J.A.M.A.*, 103, 14:1061 (Oct. 6), 1934.

Some Considerations About Health Insurance — Administrative problems which any project in insured medical care must face are set forth to suggest that pioneering in this social field must be guided by critical appraisal and research.

DAVIS, M. M. *Sickness Insurance and Medical Care*. *Milbank Quart.*, 12, 4:287 (Oct.), 1934.

Vaccination at Birth—Vaccination of the new-born baby is a practical procedure, though the newly-born child is resistant to infection with the virus. It need not be done at birth if it can be assured at 3 to 6 months.

DONNALLY, H. H.; and NICHOLSON, M. M. *A Study of Vaccination in Five Hundred New-born Infants*. *J.A.M.A.*, 103, 17:1269 (Oct. 27), 1934.

In Which Families Does Case-Finding Pay?—Accurately kept records indicate that it costs so much to discover adult type tuberculosis by tracing tuberculin positive groups of children that intensive case-finding seems uneconomic. However, this is not true of active pulmonary or tuberculous meningitis cases. These should have prompt follow-up.

EDWARDS, H. R., and UNZICKER, G. *A Cost Analysis of Clearing Tuberculosis Family Contacts*. *Milbank Quart.*, 12, 4:306 (Oct.), 1934.

Spreading Scarlet Fever—Patients with uncomplicated cases of scarlet fever may be as dangerous carriers as those with complications. The authors believe that quarantine, of any length,

will not control scarlet fever and that the hope lies in active immunization.

HOYNE, A. L., and BAILEY, J. H. The Secondary Case of Scarlet Fever. *J.A.M.A.*, 103, 14:1051 (Oct. 6), 1934.

Expanding Conception of School Child Hygiene—Ten factors in the success of the school health program are considered in some detail to present a useful bird's-eye-view of school child health administration.

IRELAND, I. G. Essentials of the School Health Program. *J. Health & Physical Education*, 5, 7:15 (Sept.), 1934.

A Slow Start for a Long Race—These are significant findings: the rat's life span is extended if the animal growth is retarded by inadequate calories (but sufficient essential nutrients) in youth.

McCAY, C. M., and CROWELL, M. F. Prolonging the Life Span. *Scient. Month.*, 39, 5:405 (Nov.), 1934.

Psittacosis Highly Infectious—The story of 11 laboratory workers who came down with psittacosis illustrates the unusual infectiousness of the disease, for only 2 were in contact with infected birds, though all were in the same building.

McCoy, G. W. Psittacosis Among the Personnel of the Hygienic Laboratory. *J. Infect. Dis.*, 55, 2:156 (Sept.-Oct.), 1934.

Rural Health Yardstick—This survey of a rural health administrative unit to determine the health problems of the peoples involved, the quality and quantity of service rendered, the relationship of the program to the needs of the community, and the specific effect, if any, upon individual health, should prove a most valuable measure of this still largely unsolved problem. The

answers will be found in subsequent papers to appear in series.

MOUNTIN, J. W. Effectiveness and Economy of County Health Department Practice. *Pub. Health Rep.*, 49, 42:1232 (Oct. 19), 1934.

Against Tuberculosis Vaccination—Further improvement in tuberculosis mortality rates must come through better epidemiology not vaccination, asserts the author in reviewing the history of tuberculosis immunization.

PETROFF, S. A. Anti-Tuberculosis Vaccination. *New Eng. J. Med.*, 211, 15:677 (Oct. 11), 1934.

Controlling Gonorrhea and Syphilis—Epidemiology and health education, the hare and the tortoise of all communicable disease prevention, are summarized in their applicability to venereal disease control. A stimulating paper.

STOKES, J. H. Public Health and Social Hygiene. *Pub. Health Nurs.*, 26, 10:535 (Oct.), 1934.

Athletes' Hearts—Enlarged hearts were found in about half the ricksha pullers examined, a condition appearing to be a physiologic response to rapid exertion carried on daily for years. There is no indication that the resulting enlargement predisposes to disease.

TUNG, C. L., et al. The Hearts of Ricksha Pullers. *Am. Heart J.*, 10, 1:79 (Oct.), 1934.

Telling 'Em About Health—Analyzing the elements of a community health education program, the author presents a useful check to be used to measure any community project in health promotion.

ZIMAND, S. An Organized Community Health Education Program. *Milbank Quart.*, 12, 4:329 (Oct.), 1934.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Wade H. Anderson, M.D., Wilson, N. C.,
County Health Officer
A. F. Branton, M.D., Willmar Clinic, Willmar,
Minn., Health Officer
Frederick Frueholz, M.D., 305 S. Seguin Ave.,
New Braunfels, Tex., City Health Officer
George C. Halley, M.D., C.P.H., 111 Second
St., W., Twin Falls, Idaho
Paul E. Mischler, D.O., City Hall, Zion, Ill.,
Commissioner of Public Health
James M. Mott, M.D., 1035 Massachusetts
St., Lawrence, Kans., Superintendent of
Public Health
F. R. Tucker, M.D., Nacogdoches, Tex., City
Health Officer
William S. Yates, M.D., Junction City, Kans.,
County Health Officer

Laboratory Section

Martin Frobisher, Jr., D.Sc., 615 N. Wolfe
St., Baltimore, Md., Director of Labora-
tories, Eastern Health District, Johns Hop-
kins University
Meridian R. Greene, Sc.D., Jewish Hospital
of Brooklyn, Brooklyn, N. Y., Research
Associate, Pediatric Research Laboratory
James D. Reid, Sc.D., 611 W. 30th St., Rich-
mond, Va., Bacteriologist, City Board of
Health

Vital Statistics Section

William F. Lunsford, M.D., M.P.H., State
Dept. of Health, Jefferson City, Mo., Sta-
tistician, charge of Bureau of Vital Statistics

Public Health Engineering Section

Bural Kessens, 7822 Cornell Ave., Chicago, Ill.,
Junior Assistant Sanitary Engineer, City
Board of Health
C. Herbert Moore, Congress Hotel, Chicago,
Ill., Sanitary Engineer
Harvey C. Rossing, 1923 S. Central Park Ave.,
Chicago, Ill., Ventilation Division, City
Board of Health

Child Hygiene Section

Herman S. Gove, M.D., State Board of

Health, Jefferson City, Mo., Director,
Division of Child Hygiene
Edward L. Russell, M.D., Orange County
Health Dept., Santa Ana, Calif., Director,
Division of Child Hygiene
Abram L. Van Horn, M.D., State Office Bldg.,
Columbus, O., Chief, Bureau of Child
Hygiene

Food and Nutrition Section

Jesse J. Frey, 425 Battery St., San Francisco,
Calif., General Sales Manager, Golden State
Co., Ltd.

Public Health Education Section

Isabelle Blumenthal, M.D., 100 West 59 St.,
New York, N. Y.
Vera McCrea, Dairymen's League Coöperative
Assn., 11 W. 42 St., New York, N. Y.,
Director, Health Education Department
Samuel G. Paul, M.D., Boston Bldg., Salt
Lake City, Utah, Medical Director, City
Schools
E. Frances Rodgers Annis, 5101 Crenshaw
Blvd., Los Angeles, Calif., Public Health
Chairman, Women's Auxiliary, Parent-
Teachers Assn.

Public Health Nursing Section

Lona C. Dunham, R.N., 314 E. Union St.,
Pasadena, Calif., Director of Nursing Ser-
vice, Visiting Nurse Assn.
Matilda Harris, R.N., 3900 La Cresta, Oak-
land, Calif., Chief Nurse, Alameda County
Health Dept.
Mae E. Mathers, R.N., Box 293, Ashland, Va.,
Red Cross Public Health Nursing Service,
Hanover County
Ellie C. Nelson, R.N., 41 Church St., Charles-
ton, S. C., Supervising Nurse, City Dept. of
Health
Mary B. Tinsley, Wytheville, Va., Red Cross
Public Health Nurse

Epidemiology Section

Hyman I. Vener, M.D., 1531 Purdue Ave.,
West Los Angeles, Calif., Member, Attend-

ing Staff, Communicable Diseases Unit, Los Angeles County General Hospital, Unit # 1

Unaffiliated

Mary S. Epstein, M.A., 222 E. 82 St., New York, N. Y., Instructor, Public Health and Hygiene, Hunter College

APPLICANTS FOR FELLOWSHIP

Health Officers Section—Gregoire Fere Amyot, M.B., D.P.H., North Vancouver, B. C.; Reginald M. Atwater, M.D., Dr.P.H., Olean, N. Y.; Ira Otis Church, M.D., C.P.H., Oakland, Calif.; Wilton Lee Halverson, M.D., Dr.P.H., Pasadena, Calif.

Laboratory Section—F. D. Pease, M.D., Missoula, Mont.

Industrial Hygiene Section—Rollo Herbert Britten, A.B., Cherrydale, Va.; William Jacobsohn, M.D., New York, N. Y.; Thomas McCance Mabon, M.D., Pittsburgh, Pa.; Sophie Rabinoff, M.D., New York, N. Y.

Food and Nutrition Section—Marietta Eichelberger, M.S., Ph.D., Chicago, Ill.

Public Health Education Section—Edna A. Gerken, C.P.H., Manila, P. I.; Jacob M. Wisan, D.D.S., Elizabeth, N. J.

Epidemiology Section—G. Foard McGinnes, M.D., Dr.P.H., Richmond, Va.; E. K. Musson, M.D., M.P.H., Jefferson City, Mo.

Unaffiliated—Otto C. Murphy, Kansas City, Mo.; Edward Lacy Pettibone, D.D.S., Cleveland, O.; James Gayley Townsend, M.D., Washington, D.C.; Frances Stern, Boston, Mass.

DECEASED MEMBERS

Jorge Le-Roy, M.D., Habana, Cuba, Elected Member 1911, Fellow 1923

E. Linwood Cornman, V.M.D., Marietta, Pa., Elected Member 1926 (Associate)

Henry A. Cotton, M.D., Trenton, N. J., Elected Member 1932

Charles W. Many, M.D., Doylestown, Pa., Elected Member 1917

Herbert C. Ober, M.D., D.M.D., Newton, Mass., Elected Member 1932

George W. Fuller, New York, N. Y., Elected Member 1915, Fellow 1922.

H. L. Abramson, M.D., St. John, N. B., Canada, Elected Member 1919

Carroll W. Eddy, D.V.M., Cleveland, O., Elected Member 1926

M. B. Harutun, M.D., Joplin, Mo., Elected Member 1920, Fellow 1923

George T. Lennon, Haverhill, Mass., Elected Member 1918

Thomas J. Strauch, Richmond, Va., Elected Member 1919

SOUTHERN BRANCH A.P.H.A.

At its third annual meeting in San Antonio, Tex., November 13-16, the Southern Branch A.P.H.A. elected the following officers:

President, C. E. Waller, M.D., Washington, D. C.

1st Vice-President, V. M. Ehlers, Austin, Tex.

2nd Vice-President, I. C. Riggins, M.D., Richmond, Va.

3rd Vice-President, Ruth Mettinger, R.N., Jacksonville, Fla.

Secretary-Treasurer, G. F. McGinnes, M.D., Richmond, Va.

BACK NUMBERS WANTED

Readers of *The American Journal of Public Health* are asked to send spare copies of the January, 1928, and of the January, 1933, issue to the American Public Health Association, 50 West 50th Street, New York, N. Y., as these issues are out of stock. These will be much appreciated, and reimbursement of postage will be made in each case.

NEWS FROM THE FIELD

THE MICHIGAN PUBLIC HEALTH CONFERENCE

A LARGE and enthusiastic group of health workers gathered at the Hotel Olds in Lansing on November 7, 8, and 9, for the 14th Annual Public Health Conference conducted by the Michigan Department of Health and the Michigan Public Health Association.

By noon on the 7th, 291 persons had registered, although the first session was not scheduled until 2.00 P.M. This was opened by C. C. Slemons, M.D., State Health Commissioner. After a brief welcoming address, he introduced the speaker of the afternoon, Carl V. Weller, M.D., Professor of Pathology at the University of Michigan, who spoke on "Cancer as a Public Health Problem," to an audience numbering more than 400. Thereafter, the assembly divided into specialized groups and attended the arranged round tables for health officers, public health nurses, sanitary officers and laboratory directors.

The intentness of the various audiences was noteworthy, and the emptiness of the hotel lobby and corridors for the entire afternoon provided significant evidence of the pulling power of the programs.

Informal dinner meetings preceded the evening session which was presided over by Chalmers J. Lyons, D.D.Sc., Professor of Oral Surgery at the University of Michigan and a Member of the State Council of Health. Samuel M. Gordon, Ph.D., Secretary, Council on Dental Therapeutics, American Dental Association, was the speaker and his subject was "Mouth Washes and Dentifrices, Their Advertising, and Public Health Work."

Louis J. Hirschman, M.D., Detroit, a Member of the State Council of

Health, opened the Thursday morning meeting promptly at 9.00 A.M. "Welfare Relief in Michigan" was presented by the State Relief Administrator, William Haber. Two papers on Vital Statistics followed, one by W. J. V. Deacon, M.D., the other by T. F. Murphy, M.D. Dr. B. W. Carey, President of the Michigan Public Health Association, delivered the Presidential Address at the luncheon business meeting of the organization.

The afternoon program was devoted to "The Rôle of Nutrition in Public Health." Robert B. Harkness, M.D., Houghton, President of the State Council of Health, presided. The speakers were J. A. Johnson, M.D., Helen S. Mitchell, Ph.D., Lelia McGuire and Don J. Barnes, M.D.

The Conference Dinner on Thursday evening was very well attended. George J. Curry, M.D., Flint, Member of the State Council of Health, was Toastmaster and the speaker was Shirley W. Allen, Professor of Forestry, University of Michigan, on the topic "Fighting Waste with the CCC."

The Friday morning session was given over to a program of miscellaneous technical subjects including tuberculosis, preparation, standardization, and use of alum precipitated toxoid, immunization against poliomyelitis, streptococcic sore throat. Such experts as Drs. Forsbeck, Bunney, Newitt, Littlejohn, Mr. T. J. Werle, Drs. Cummings and Barrett were the speakers.

Held coincidentally with the Conference was a meeting of the Michigan Association of School Physicians, who conducted a luncheon meeting and an afternoon session on school health problems, and of the State Organization of Public Health Nurses.

The Conference adjourned at noon on Friday. Praise and credit go to Dr. Slemons and the members of his staff who assisted him in preparing the program, in making the excellent arrangements and, most particularly, for assembling such a large number of interested and interesting people at a state meeting.

NEW JERSEY HEALTH AND SANITARY ASSOCIATION

THE 60th anniversary of the New Jersey Health and Sanitary Association was observed at Asbury Park on November 16 and 17. A most interesting program had been prepared and a goodly number were there to appreciate it.

On Friday afternoon, two sessions were held, one a General Session at which Russell Van Nest Black, Dr. Allen G. Ireland, and Dr. LeRoy A. Wilkes, F.A.P.H.A., discussed the Planned Development of the State of New Jersey and Its Relation to General Public Welfare, The New Jersey School Health Program, and The Medical Society of New Jersey Organizes to Improve Community Health Services, respectively. In addition, a special session on various problems in sewage disposal was held for the benefit of those concerned.

At the Friday evening session, Dr. Thomas Parran, Jr., F.A.P.H.A., was the guest speaker discussing Health and Medical Relief in New York State. This session was widely attended by both the delegates present at the meeting and interested persons from neighboring towns.

The highlight of the evening session was the presentation of an award in the form of a bronze plaque to Dr. Theobald Smith of Princeton.

An interesting summary of the work of Dr. Theobald Smith appears in the November number of *Health Progress*, the monthly publication of the New

Jersey Health and Sanitary Association.

The Saturday morning session was given over to a round-table discussion of various association projects and an annual business meeting.

DR. THEOBALD SMITH GETS AWARD

ON November 16, the annual award for meritorious service in the fields of medicine and science, given by the New Jersey Health and Sanitary Association, was presented to Dr. Theobald Smith of the Rockefeller Institute, Princeton. It was accepted in absentia by Dr. Carl Ten Broeck, associate director of plant and animal pathology at the institute.

Dr. Smith received the Copley Medal of the British Royal Society last November in recognition of his research into diseases of animals and man. One of his most notable achievements was the discovery that Texas cattle fever was caused by the bite of an infected tick. This led the way to other discoveries of like importance in malaria infections. Dr. Smith also discovered the cause of bovine tuberculosis.

The presentation was made by James E. Brooks of Newark, president of the association. Mr. Brooks reviewed Dr. Smith's 50 years as a physician, teacher, student, and scientist, and called attention to his many achievements for the benefit of mankind and animals. The award was a bronze plaque.

In 1930 Dr. Smith was awarded the Sedgwick Memorial Medal at the A.P.H.A. meeting in Fort Worth, Tex.

\$1,000,000 FERA FUND GOES TO RURAL HEALTH

Federal Service to Aid Units in States—To make more efficient the rural health service in areas severely hit by the depression, \$1,000,000 has been allotted from Federal Emergency Relief funds to the Public Health Service.

"The Public Health Service will give financial aid through state health de-

partments toward the maintenance of existing full-time county or district health units when local funds available are insufficient to provide for adequate health service," a Treasury announcement said.

The service will undertake to establish new full-time rural units when local funds are insufficient to meet the entire cost. It will not contribute to any project in which less than 50 per cent of the cost is borne by state or local authorities.

There are 550 full-time county units, as compared with 16 in 1933. The first unit was organized in 1911 in Yakima County, Wash., State officials at that time asking federal aid in setting up an agency to combat typhoid fever.

"It is estimated that less than 25 per cent of the rural population of the country has the benefit of full-time health service at the present time," the Treasury said.—*New York Times*, Oct. 24, 1934.

RECORD FORMS FOR TUBERCULOSIS SANATORIA

FOR the first time it is now possible for tuberculosis sanatoria to keep uniform and complete records of all material facts about their patients, available at all times for instant consultation. This important improvement in health bookkeeping is a result of 2 years' work done by a committee of the American Sanatorium Association, assisted in a secretarial capacity by members of the staff of the National Tuberculosis Association. The 23 new forms which have been prepared are obtainable from the Livingston Press, Livingston, N. Y.

Forms are numbered and designated, as follows:

1. History—4 pages
- 1A. History
2. Examination
3. Nose, Throat, Ear, and Eye—Teeth
4. Physician's Orders

5. Nurse's Record
6. Weight Chart
7. Temperature, Pulse, and Respiration
8. Laboratory Examinations (Sputum, etc.)
9. Laboratory Examinations (Blood, etc.)
10. X-ray
11. Re-examination
12. Pneumothorax
13. Exercise Chart
14. Heliotherapy
15. Prescription for Physiotherapy
16. Consultation
17. Operations
18. Tuberculous Empyema
19. Permission for Autopsy
20. Admissions—Discharges
21. Statistical Summary on Discharge
22. Blank form (heading only)
23. File folder

DIRECTORY OF HEALTH OFFICERS

THE U. S. Public Health Service has published a Directory of the Full Time County Health Officers in the United States, in *Public Health Reports* for September 28, page 1134, compiled from data furnished by state Health Officers as of Jan. 1, 1934.

Similar directories have been published annually since 1922, except for 1932, when funds were not available.

CHILD LABOR DAY—JANUARY 26-28

THE last week end of January, 1935, has been designated for the observance of Child Labor Day by the National Child Labor Committee, following a custom of nearly 30 years.

The keynote this year will be ratification of the Federal Child Labor Amendment. This Amendment is now before the states for ratification; it is stated to be merely an enabling act specifically empowering Congress to legislate on the subject.

AMERICAN AMBULANCE MAKES DEBUT IN JERUSALEM

OX carts and donkeys as transports for the sick of Jerusalem will give way to a brand new Ford ambulance fully equipped in accordance with New York hospital standards, which has just

arrived in the Palestine capital, according to word received by Hadassah, the Women's Zionist Organization of America.

The ambulance, said to be the first ever to appear in the Holy Land, was consigned to the Rothschild-Hadassah Hospital. It was shipped from New York by Mrs. Rive K. Weinstein, sister of Dr. Ira I. Kaplan, head of the cancer division of the New York Department of Hospitals.

HYGIENE INFORMATION CENTER IN FRANCE

A FREE hygiene information center, the first of its kind in France, was recently opened in a crowded district of Paris by a private physician. The center will give information on such subjects as personal hygiene, housing hygiene, physical exercise, swimming pools, infant and child hygiene, hygiene of work, measures against venereal and other contagious diseases, and health legislation, and will supply the addresses of welfare agencies.

The physicians at the center are prohibited from giving treatment or advice to ill persons.—*Le Nourrisson*, Paris, No. 4, July, 1934.

ROCKEFELLER FOUNDATION

THE Rockefeller Foundation expended for public health work during the year the sum of \$3,286,-063.01. It supported laboratories for yellow fever research in Lagos, Nigeria; Bahia, Brazil; and New York City. It completed, in coöperation with various governments of West Africa, an extensive survey which disclosed the areas in Africa where yellow fever occurs; assisted the governments of Brazil and Bolivia in an extensive program of yellow fever control; conducted experiments and studies on the vaccine and virus of yellow fever and on the mosquito vectors of this disease; aided three states in the United States and

seventeen foreign governments in anti-malaria work; carried out malaria studies and surveys in various parts of the world; engaged in studies of hook-worm disease in Palestine, Egypt, Straits Settlements, and Puerto Rico; supported studies of *Endamoeba histolytica*, Rocky Mountain spotted fever, tuberculosis, sprue anemia, filariasis, schistosomiasis, and the diseases affecting the races of the Pacific; aided the government of India in conducting experiments on the disposal of refuse; sponsored studies of statistical epidemiology; contributed toward the development of state and local health services of fifteen European countries, the League of Nations, five Far Eastern countries, the government of the South Pacific Islands, six countries of the Caribbean region, two countries of South America, and the governments of Mexico and Canada; gave assistance to the central health administrations of fourteen states in the United States and to the local health administrations of twenty-three states of the United States, four provinces of Canada, and five areas in Mexico, and provided funds for local health units in fourteen other countries; directed the studies of 197 fellows in public health, thirty-two nursing fellows, and six nurse visitors; provided financial aid to former fellows in carrying out special studies; and contributed toward the support of schools of hygiene and public health and of centers of public health training in Japan, Puerto Rico, Central America, South America, Europe, and the United States.—Excerpt from Report for 1933.

CHANGES IN THE COST OF LIVING, OCTOBER, 1934

THE first decline since April of this year in the cost of living of wage earners in the United States was noted in October, according to the indexes computed by the National Industrial Conference Board. Increases in the cost of some major groups of expendi-

ture were offset by declines in others; the net result was a slight decrease of 0.1 per cent. Living costs in October were 3.7 per cent higher than in October, 1933, but 19.9 per cent lower than in October, 1929.

The purchasing value of the dollar was 123.6 cents in October as compared with 123.5 cents in September, 139.9 cents in April, 1933, and 100 cents in 1923.

Food prices declined 1.0 per cent from September to October which is contrary to the usual seasonal upward movement at this time of the year and also in sharp contrast to the increase of 4.4 per cent which took place from August to September. There has been an increase of 7.8 per cent in food prices since October, 1933, and a decrease of 28.0 per cent since October, 1929.

Rents continued their upward trend, rising 0.6 per cent from September to October, which made them 5.1 per cent higher than in October, 1933, but still 27.9 per cent lower than in October, 1929.

Clothing prices changed only to a small degree from September to October, both men's and women's clothing declining 0.1 per cent. While clothing prices in October were distinctly higher, namely, 25.8 per cent, than in June, 1933, when the upward movement in clothing prices was first observed, as compared with October, 1933, there has been a decline of 0.3 per cent and they were still 21.7 per cent below the level of October, 1929.

Coal prices advanced 0.2 per cent from September to October, less than is usually observed in the fall. Coal prices in October were 2.1 per cent higher than a year ago but 7.3 per cent lower than five years ago.

The index of the cost of sundries was 0.4 per cent higher in October than in September because of increases in the prices of admissions to motion picture

theatres, as well as in prices of tobacco and house furnishings. The data in regard to admissions to motion picture houses are obtained in October of each year. The cost of sundries in October was 1.5 per cent above that of October, 1933, and 6.5 per cent below October, 1929.—National Industrial Conference Board Release, Nov. 13, 1934.

MATERNAL WELFARE IN ITALY

AS a measure against the high maternal mortality rate in Italy, the Minister of the Interior has issued a circular to the various prefects urging them to establish sufficient prenatal centers and maternity hospitals and to investigate every death of a mother or baby during confinement or soon afterward. The Minister points out the importance of providing obstetric service at home, including the necessary materials for women of small means. For the improvement of the obstetric service the Minister urges the prefects to coöperate with the provincial branches of the National Bureau for Maternal and Child Welfare, giving special attention to rural communities.—*Difesa Sociale*, Rome, May, 1934.

DEATH OF PROFESSOR P. F. NICHOLS

THE University of California announces the death of Professor Paul F. Nichols, of the Fruit Products Staff of the College of Agriculture.

From 1918 to 1924 he was engaged in fruit and vegetable dehydration investigation of the U. S. Department of Agriculture on the Pacific Coast. From 1924 to 1926 he served as chief chemist in standardization investigations for the Sun-Maid Raisin Growers Association at Fresno, Calif. Since that time he has been in charge of fruit drying and dried fruit packaging investigations at the University of California in Berkeley.

He was a member of the American Public Health Association and delivered a paper at the Pasadena meeting which was published in the November *Journal*.
